ABSTRACT

Results of oceanographic surveys off the Grand Banks of Newfoundland from April through June 1972 in support of International Ice Patrol and twelve occupations of Standard Sections A1-A4 are discussed. Analysis includes vertical temperature and salinity profiles for each section as well as dynamic-topographic charts for each Ice Patrol survey. Normal dynamic topography charts of the Grand Banks region are updated. Results are similar to those obtained by Soule (1964). Finally there is a discussion of the oceanographic and meteorological conditions which caused more icebergs to drift south of 48°N in 1972 than in any previous year in Ice Patrol history. These conditions include iceberg supply, wind, currents, waves/sea ice, sea temperatures, air temperatures, and precipitation. It is concluded that the single most important factor effecting these conditions is the location and intensity of the Icelandic low.

OCEANOGRAPHY OF THE GRAND BANKS REGION OF NEWFOUNDLAND

March 1971—December 1972

Robert W. Scobie¹

INTRODUCTION

The iceberg threat to North Atlantic shipping was more severe in 1972 than in any other year in International Ice Patrol (IIP) history. The ice season officially extended from 29 February to 4 September—the longest ever. During that period, a record 1587 icebergs were reported south of 48°N. This surpassed the previous high of 1320 icebergs sighted in 1929. In 1972 icebergs were reported as far east as 47°02'N, 36°59'W and as far south as 39°57'N, 45°06'W. For the first time since 1959, conditions were severe enough to require a surface patrol to standby the southernmost iceberg. This duty was shared by several Coast Guard cutters from 25 April until 25 July when icebergs were no longer a threat below 43°N.

Oceanographic Operations

During the months of April, May, and June, when the iceberg threat was greatest, three oceanographic cruises were conducted to the area immediately eastward of the Grand Banks of Newfoundland by the USCGC EVERGREEN (WAGO-295). The purpose of these cruises was two-fold. First, it was to provide Commander, International Ice Patrol (CIIP) with real-time oceanographic data for predicting iceberg drift in the North Atlantic Ocean. Second, it was to support U.S. Coast Guard oceanographic research programs. The crew of CGC EVERGREEN was augmented with a field party of scientists and technicians from the U.S. Coast Guard Oceanographic Unit (CG OCEANOU) on each of these cruises.

Itinerary

On 3 April the CGC EVERGREEN departed its homeport of Boston, Massachusetts on a 21-day cruise which included a one day port call at St. John's Newfoundland. The oceanographic work conducted on this cruise consisted of 72 STD stations taken along 7 standard Ice Patrol sections extending from A2 to A4 (fig. 1). Several casts were taken at other than the desired position because of locally heavy concentrations of icebergs.

During the second cruise of 17 days, which began on 5 May, 53 STD stations were occupied on six standard sections from A4 to A2B. The final CGC EVERGREEN cruise of the season commenced on 3 June. After completing section A4 and part of section A3C, a large dead-in-the-water contact appeared on the radar. Proceeding slowly through thick fog, CGC EVERGREEN was able to identify the contact as a large tabular iceberg located at 42°42'N, 49°20'W. Commander International Ice Patrol then ordered CGC EVERGREEN to standby this iceberg and assume full duties of surface patrol vessel. Thus from 7 June until 15 June, oceanographic work was confined to the area around the iceberg. During this period STD casts, XBT casts, and photographs of the iceberg were taken. After being relieved of this responsibility, an abbreviated survey along 4 sections from A3B to A2 was conducted. Of the 54 STD casts taken during this cruise, 46 were taken near the large iceberg. The CGC EVERGREEN returned to Boston on 22 June.

¹U.S. Coast Guard Oceanographic Unit, Bldg. 159-E, Navy Yard Annex, Washington, D.C. 20590.

Other Occupations of Standard Sections

Twelve other occupations of Coast Guard standard sections A1-A4 are listed in Appendix A. These were conducted by Coast Guard cut-

ters traveling to or from ocean station patrols. The 1971 occupations are included as they have not previously been reported in the CG-373 Series.

INSTRUMENTATION AND METHODS

International Ice Patrol Cruises

Data from all 179 oceanographic stations taken during the three 1972 Ice Patrol cruises aboard CGC EVERGREEN were obtained using a Plessey Environmental Systems, Model 9040, S/T/D Environmental Profiling System (STD). The Plessey Environmental Systems, Model 8114A, Digital Data Logger (DDL) was used to record these data on magnetic tape. However, as CGC EVERGREEN did not have the on board computer capability to process DDL tapes, it was necessary to read the STD analog traces and to transmit the data including quality control temperatures and salinities to CG OCEANOU for real-time processing. This processing was accomplished with a Honeywell DDP-516 computer utilizing the programs described by Hislop (1973). Following the Ice Patrol season, the DDL tapes were processed on the Control Data Corporation (CDC) 3300 computer using the procedures described by Rosebrook (1974).

A Niskin bottle, equipped with two protected and two unprotected deep sea reversing thermometers, was attached immediately above the underwater sensing unit on all deep stations for

quality control. Conductivity ratios of these samples were determined on board CGC EVERGREEN using a portable inductive salinometer and were converted to salinities using formulae published in the International Oceanographic Tables (1966). Temperatures were also processed on board CGC EVERGREEN with a Dietzgen Model 7410-PA programmable calculator with programs developed at CG OCEANOU. Dynamic heights in shallow water were calculated using the modified Helland-Hansen method described by Kollmeyer et al., (1967).

Occupation of Standard Sections

Data from the 12 occupations of standard sections A1-A4 reported here were obtained from either STD or Nansen casts depending on how each ship was outfitted. The cast procedures outlined in the Manual for Oceanographic Operations (CG-410) were followed during these occupations. Station data were processed using conventional CG OCEANOU procedures. Vertical temperature and salinity profiles for these occupations are presented as Figures 2 through 24. Similar profiles for all IIP occupations of A2, A3, and A4 are also presented (figs. 25 through 38).

UPDATING THE NORMAL DYNAMIC TOPOGRAPHY CHARTS

Background

Floyd M. Soule, who was a prominent member of International Ice Patrol for a period spanning more than 30 years, published the original normal dynamic topography charts of the Grand Banks area (Soule, 1964). These charts were developed primarily for use by Commander, International Ice Patrol (CIIIP). Before explaining how they were updated, the evolution and use of these charts will be reviewed.

The 15 April 1912 sinking of the luxury liner *Titanic* following her collision with an iceberg at $41^{\circ}16'N$, $50^{\circ}14'W$, some 300 miles south of Newfoundland, prompted international shipping interests to demand that an organization be formed to continually advise the mariner of the iceberg danger. The result of this outcry was the establishment of the International Ice Patrol by the International Convention for the Safety of Life At Sea (SOLAS) in 1913. This service, financed by SOLAS member nations and operated by the U.S. Coast Guard, is designed to advise the mariner of any iceberg danger, as well as to conduct oceanographic research, in the area of the Grand Banks. The oceanographic conditions in this area are very complex as it is the confluence region of the cold southerly flowing Labrador Current and the warm northerly flowing North Atlantic Current.

During the first few years of Ice Patrol, the emphasis was placed on ice observation and advisories. As a result, the oceanographic data collected was quite sparse and of only limited value. However, as oceanographic techniques and equipment improved, it became apparent that oceanographic operations could be valuable to CIIIP. For the first time in 1931 an Ice Patrol vessel was devoted to oceanographic research, and by 1934 data were being collected in a systematic and concentrated manner.

That year, two significant changes in IIP operations occurred. First the Wenner Salinity Bridge replaced the tedious titration method

previously used to determine salinity. This greatly improved the accuracy and ease with which salinity samples could be determined (Soule and Hoyle, 1935). This instrument was used exclusively through the 1961 ice season. Then after two years of comparative testing, it was phased out and replaced by commercially produced portable inductive salinometers. The second change in 1934 was the replacement of the Jacobsen and Jensen method of determining dynamic heights in shallow water with the Helland-Hansen method (Soule and Hoyle, 1935). This method is still used, although it has been slightly modified for adaption to computer usage (Kollmeyer, et al., 1967).

Since 1934 only one other major change in the collection and processing of data has been made. In 1966, the STD replaced the Nansen bottle as the primary sampling device. However, Nansen bottles equipped with deep sea reversing thermometers continue to be used to quality control STD data.

Use

Every year that IIP has been conducted since 1934, at least some time has been spent surveying the northeastern, eastern, and southern slopes of the Grand Banks. As the general oceanic circulation in this area is similar from year to year, Soule felt that monthly normal dynamic topography charts would be of use to CIIIP. They definitely have been. At times during the peak of the ice season (April-July), when no data are being collected, CIIIP utilizes the normal charts as an aid in predicting iceberg drift.

Update

Soule's normal charts were based on 22 years of data collected from 1934-1941 and 1949-1961; IIP was suspended during World War II. For this first revision of the normal charts, data from 1962 through 1972 were added to the original data base. The data used in this revision consist of

- April—Forty-three surveys (no data from 1969)
- May—Forty-five surveys (no data from 1955 and 1969)
- June—Twenty-nine surveys (no data from 1941, 1951, 1957, 1963, 1965, 1966, 1969-1971)
- July—(no data prior to WW II nor from 1949, 1950, 1954, 1958, 1959, 1965, 1966, 1968-1972).

The July chart is somewhat abbreviated covering only a small area east of Cape Bonavista. From 1934 through 1972, no other areas were surveyed during July.

Data for the revised charts were processed exactly in the same manner as described by Soule (1964). Briefly, dynamic height values, dynamic height of the sea surface relative to the 1000 decibar surface, for each survey were computed at twenty minute intervals of latitude and longitude in the area surveyed. The dynamic heights at each interval were averaged for each month with equal weight given to each year rather than each survey. These average values were used to develop the monthly normal charts (figs. 41, 44, 47, 50). A standard deviation was computed at each interval. All locations with at least five surveys were used to contour a field of standard deviation for each month (figs. 42, 45, 48, 51). Finally a chart for each month (figs. 43, 46, 49, 52) was prepared which indicates data distribution and computed results at each interval according to the following format:

| | |
|---|--|
| Individual Surveys | Years Represented |
| Standard Deviation in Dynamic Millimeters | Average Dynamic Height of the Sea Surface Relative to the 1,000 Decibar Surface in Dynamic Meters minus 970.00 |

General Comments

The Labrador and North Atlantic Currents, as well as a region of low dynamic topography between them, are clearly present on the April,

May, and June normal charts. Using information from recent Canadian Hydrographic Service charts, it is clear that the bottom topography affects the flow of both currents. The steepest gradients of the Labrador Current closely parallel the bottom contours along the eastern slope of the Grand Banks implying that the Grand Banks acts as a lateral boundary of this current. The flow of the North Atlantic Current is influenced as it passes over and around the northern end of the Newfoundland Ridge which is located south of the Tail of the Bank.

Current direction can be inferred quite realistically from the normal charts as being parallel to the isopleths of dynamic heights. However, geostrophic speeds are not as easily determined. Due to the averaging process, speeds calculated by taking measurements perpendicular to the isopleths of dynamic height are lower than those that actually exist in the Labrador Current. Thus the current as calculated from the normal charts only approaches a maximum of 40 cm/sec in a few extreme cases in the core of the Labrador Current. Whereas experiments such as those conducted by International Ice Patrol (direct measurement by parachute drogues) in 1966 (Wolford, 1969) indicate the speed of the Labrador Current actually varies from 50 to over 100 cm/sec. Thus when using the normal charts, one must be careful not to underestimate the current speed.

The fact that these revised charts closely resemble Soule's adds validity to the assumption that the general circulation in this area is basically the same from year to year. This is especially true for the core of the Labrador Current and the dynamic "trough" to the east of this current. Standard deviations are greatest near 41°N , 50°W and 42.5°N , 46°W . These are the areas which contain meanders of the North Atlantic Current. Annual changes combined with steep gradients result in standard deviations being as high as 20 centimeters in May.

1972 DYNAMIC TOPOGRAPHY SURVEYS

As has been the practice of IIP for many years, the 1000 decibar surface was used as a reference level in calculating dynamic heights from the 1972 data. Experiments as recent as 1970 (Ettle and Wolford, 1972) have shown that this level is suitable for IIP work. Thus, it is

possible to compare the dynamic topography of each 1972 survey (figs. 53, 54, and 55) directly with past surveys and the monthly normal charts. Such comparisons appear in later sections.

1972 ICEBERG STUDIES

Three icebergs were tracked by Coast Guard cutters, while acting as the surface patrol vessel, during the 1972 ice season. From 5 to 11 May, the CGC VIGOROUS (WMEC-627) tracked a medium iceberg using celestial fixes as the primary means of navigation. The May 1972 oceanographic survey (fig. 54) did not cover the area where this iceberg was drifting. However, from the May normal chart (fig. 44) and the May 1972 survey it is apparent that this iceberg was located well into the North Atlantic Current when it was being studied. This iceberg, drifting an average of more than 30 nmi per day, was predominantly effected by the North Atlantic Current (fig. 56). Only during the early part of the study period did the wind, which averaged 17 knts from 224°T (fig. 56), have any significant effect on the iceberg's drift.

CGC EVERGREEN tracked two icebergs—a large tabular iceberg from 8 to 15 June and a small iceberg from 9 to 13 June. Due to heavy fog, Loran A, with an accuracy of 3–5 miles, was used for positioning during this study. These icebergs drifted around in the same general area during the study period (fig. 57). These drifts were in great contrast to the one in May. During this study four sets of four STD stations were taken around the large iceberg. The general flow of the current in this area was southerly

(fig. 58), although not nearly as constant as in the core of the Labrador Current which existed farther to the north. From the iceberg drift, it appears that the effect on these icebergs from the southerly flowing current was to a great degree offset by the effect of the wind (fig. 57), which averaged 14 knts from 188°T during the large iceberg study and 195°T at 19 knts during the small iceberg study.

Four expendable bathythermograph (XBT) sections were conducted at two-day intervals. Each section, consisting of 10 XBTS, was on a constant bearing from the large iceberg ranging from 10 to 500 yards from the iceberg. The purpose of this experiment was to check for horizontal temperature gradients, previously mentioned by Kollmeyer et al. 1966, along each section. However, no gradient was apparent on any of these sections.

From photographs taken around an iceberg, mass determinations of that iceberg can be made. It was hoped that this could be accomplished several times during the drift study of the large iceberg, for such a study could yield information on the rate of deterioration of the iceberg. However, due to poor visibility, a good set of photographs was obtained only at the end of the drift study. At that time it was determined that the iceberg had a mass of approximately 3×10^9 kgs.

DISCUSSION OF 1972 ICE CONDITIONS

Although the number of icebergs which annually drift south of 48°N (fig. 59) fluctuates considerably, this number generally declined during the 40 years prior to 1972 (Table 1). In

TABLE 1—Yearly Average Number of the Icebergs South of 48°N

| Years | Average # of Icebergs |
|-----------|-----------------------|
| 1932-1941 | 419.1 |
| 1942-1951 | 418.1 |
| 1952-1961 | 251.6 |
| 1962-1971 | 146.3 |

fact, during that entire period, only in 1945 did this number exceed 1000. Why then did this trend come to such an abrupt end in 1972? Primarily it was a result of substantial changes in oceanographic and meteorological conditions during late 1971 and early 1972. These conditions directly affected the following factors that in turn determine the iceberg count on the Grand Banks:

- Supply of icebergs
- Wind
- Current
- Waves/Sea Ice
- Sea Temperature
- Air Temperature
- Precipitation

Iceberg Supply

Most of the icebergs which eventually reach the Grand Banks are calved from glaciers along the west coast of Greenland. Determining the annual iceberg production of these glaciers is a difficult task complicated by the remoteness of this vast region. One census will not result in an accurate count as icebergs may survive for several years in the survey area. To obtain an accurate production figure, it is necessary to conduct several censuses over a period of years while taking into account such factors as melting and

calving of icebergs. Since such studies have not been undertaken, it is not surprising that estimates of annual iceberg production vary greatly. Wolford (1972) reports several estimates of iceberg production ranging from 7,500 to 40,000 and suggests that the higher value is more realistic. Using even the most conservative estimates, the annual supply of icebergs is substantial enough to support heavy ice seasons on the Grand Banks.

Each year HIP conducts iceberg reconnaissance flights from Newfoundland northward along the Canadian coast to estimate the severity of the upcoming ice season. A January 1972 flight covered the coastal area to Cape Dyer and a February 1972 flight terminated at Cape Chidley. Past experience indicated that only icebergs located south of these points at these respective months will reach the Grand Banks during the following ice season. The result of these 1972 flights was surprisingly low iceberg counts (fig. 60).

This apparent contradiction can be explained. The majority of iceberg drift studies conducted by HIP found icebergs advancing southward 3 to 6 miles per day. However, in some instances, advances in excess of 20 miles per day have been noted (Wolford, 1972). Under ideal conditions, as was the case in 1972, it is not unreasonable to assume that icebergs can maintain a speed of advance of 0.5 knots over a long period of time. At this rate, icebergs that were in Baffin Bay in January could reach the Grand Banks during the ice season. With the supply of icebergs in Baffin Bay estimated to be more than 40,000 at any one time (Sanderson and Davis, 1972), only a small fraction of these icebergs is needed to greatly increase the severity of the ice season. This is what is believed to have happened in 1972.

Winds

Icebergs are transported to the Grand Banks by a complex combination of wind and current.

The wind acts directly on the subaerial portion of the iceberg and indirectly on the submerged portion through the force which it imparts on the ocean surface. The prevailing winds along the eastern Canadian coast are from the northwest, which are the most favorable for transporting icebergs toward the Grand Banks. Winds from any other direction tend to impede the advance of the icebergs. Obviously the advance of icebergs would be blocked by winds from the south. Easterly winds cause the icebergs to drift toward the Canadian coast where they ground and deteriorate. Westerly winds force icebergs out of the Labrador Current into the Labrador Sea, slowing the icebergs' southern progress and exposing the icebergs to warmer water of the Labrador Sea and wave action. As Wolford (1972) points out, winds in this region are dependent on the location and intensity of the Icelandie Low. This term applies to an area where lows form and intensify rather than one particular low pressure system. Northwesterly winds increase as this low deepens. Normally this low is weak during the summer and intensifies during the winter.

Due to severe low pressure systems (fig. 61), which traversed this region during the winter of 1971-1972, the Icelandie Low was more intense than normal for every month from December 1971 through June 1972 with the exception of April 1972, when conditions were close to normal. During these months, a mean surface pressure anomaly existed as shown in January (fig. 60). Since wind anomaly is related to lines of equal pressure anomaly as winds are to isobars, Buys-Ballot's Law may be applied in determining direction of wind anomaly. During the winter of 1971-1972, the prevailing northwesterly winds were reinforced by the deeper than normal Icelandie Low. These winds were extremely favorable for iceberg drift southward along the Canadian coast.

Currents

The Baffinland and Labrador Currents transport icebergs southward toward the Grand Banks. These currents, which move much slower than the wind and are less variable, act on most of the iceberg's surface area. A well developed current system is a necessary but not sufficient condition for a heavy ice year. The Labrador Current was well developed in 1957 (Dinsmore

et al., 1958), 1958 (Dinsmore et al., 1960), and 1959 (Budinger et al., 1960), but only 1957 and 1959 were heavy ice years. In 1958 other critical factors, including warmer than normal sea surface temperatures, were unfavorable and a light year resulted. At no time has there been a heavy ice season when the Labrador Current was not well developed.

Current data along the Labrador coast are very scarce, especially in the winter months. Russian scientists conducted the only survey in this area during the winter of 1971-1972. From their 8-9 November occupation of section 8-A (fig. 63), the volume transport of the Labrador Current was determined to be 6.5 Sv; which is 30% greater than normal. Later in the same month, section 6-A (14-15 December) and section 3-A (24-25 December), both of which are farther south, were also occupied. Volume transport was only 1.1 Sv across section 6-A and 6.8 Sv which is normal, across section 3-A (Kudlo, 1973).

On 21-22 March, CGC SHERMAN (WHEC-720) occupied section A-2 (figs. 14 and 15), and the volume transport was determined to be 2.16 Sv southward and 1.07 Sv eastward. This indicated that the southerly transport had nearly doubled since the December occupation of 6-A. It should be noted that the east-west portion of A-2 is very similar to the Russian section 6-A and the British Grand Banks-Flemish Cap section (Hill et al., 1974).

During a two week period in April, each of these sections was occupied. As part of an IIP survey, section A-2 was occupied on 7-9 April (figs. 25 and 26). The southward flow was 3.71 Sv while the eastward flow was 1.70 Sv. On 10 April, the southerly flow across section 6-A was 3.03 Sv (Kudlo, 1973). Hill et al. (1974) calculated the southerly flow to be 5.27 Sv from a 17-18 April occupation of the Flemish Cap-Grand Banks section. Two factors may have been responsible for the wide range in these transport values. First, as has been noted by Morgan (1969) and other IIP authors, the volume transport of the Labrador Current may undergo large changes over a short period of time. Second, much subjectivity is required in using the geostrophic method of determining currents especially in extrapolating values in shallow water and in selecting a reference level. As the Flemish Channel is very narrow and re-

quires much extrapolation, it is felt that in this case the second reason is the primary cause of the variation in the transport values. In addition, Hill et al. (1974) modified their geostrophic values with data from current meters located along the Grand Banks-Flemish Cap section. Although the British value is much greater than the Coast Guard's, their current profiles (fig. 64 and 65) are similar. In both cases the core of the Labrador Current is just to the east of the continental slope and an anomalous northward flow is just to the west of Flemish Cap. Comparing these data with available historical data, the Russian value is slightly greater than their normal (Kudlo, 1973) and the Coast Guard figure is higher than the running average which was terminated in 1964 (Kollmeyer et al., 1965). Thus it can be said that the Labrador Current was well developed in the first part of April.

The dynamic heights from the above occupation of section A-2 and those from the remainder of the three cruises conducted for IIP were contoured and are shown in figures 53, 54, and 55. The Labrador Current was well developed as far south as the Tail of the Bank through June with currents in excess of 50 cm/sec being found in the core. The volume transports generally increased through May before slackening in June. Such conditions are extremely conductive to icebergs, southward drift.

While the flow of the Labrador Current was steady during this period, large fluctuations occurred in the North Atlantic Current and the dynamic trough region. The April dynamic topography was similar to the normal (fig. 41). However, by the May survey, conditions had changed dramatically and did not resemble either the April 1972 chart or the May normal (fig. 44). The dynamic trough had expanded and contained two distinct sections. The lower portion of the trough was adjacent to the Labrador Current as expected, but just to the east was a slightly higher portion of the trough which was dynamically flat. The temperature in this part of the trough was much higher than in the lower portion indicating that it may have been formed as a result of an eddy meander separating from the North Atlantic Current. Another unusual condition existed south of the Tail of the Bank where the flow of the Labrador Current was abruptly blocked by a meander of the North Atlantic Current indicated by the presence

of warm saline water (figs. 31 and 32). Since the June survey was abbreviated, it is impossible to determine if these conditions had returned to normal at that time.

Waves/Sea Ice

There are two ways that iceberg drift is affected by sea ice. First, surface waves are rapidly damped as they travel under this ice which reduces the eroding effect of these waves on icebergs. Second, large amounts of sea ice will keep the icebergs from drifting into bays and inlets along the coast (Schell, 1961). The presence of sea ice is an indication that the iceberg is in cold water where no deterioration will occur. From December through June, the sea ice extended farther south and east than normal (Sanderson, 1972a, Sanderson, 1972b, and Sanderson, 1972c). The greatest departure from the normal occurred in January (fig. 66), and even as late as May, sea ice remained off the coast of Newfoundland (fig. 67). Thus during the winter of 1971-1972, heavy ice conditions were such as to reduce the mortality of icebergs drifting southward along the eastern Canadian coast.

Sea Temperatures

It is obvious that with increased sea temperatures, more iceberg melting will occur. But for the entire first half of 1972 the water in the area of interest was colder than normal. It is clear from Sanderson (1972b), and Sanderson (1972c) that the average sea surface temperatures were below normal along the Labrador and eastern Newfoundland coasts for the first six months of 1972. Specific temperatures as much as 11°C colder than normal were reported in the Grand Banks area (Bailey, 1973). This unseasonably cold condition caused the 0°C sea surface isotherm to remain south of Newfoundland throughout March (fig. 68) (Royal Met. off., 1972a), and even as late as June this isotherm extended as far south as northern Newfoundland (fig. 69) (Royal Met. off., 1972b).

Colder than normal conditions also were found at depth. Burmakin (1973) noted that temperatures along sections 8-A, 7-A, 6-A, 4-A, and 3-A were between normal and 2.2°C below normal at various times from November through May in the upper 200 meters. Several IIP sections also indicate these cold conditions. The vertical temperature profile from the 7-8 April

occupation of Section A-2 gives an indication of the early extent of the Labrador Current (fig. 25). The 0°C isotherm extended to about 150 meters for nearly the entire section. The minimum water temperature was less than -1.6°C . The 0°C isotherm is significant as little iceberg melting will occur below this temperature. This cold core extended at least to the Tail of the Bank as can be seen in the vertical temperature profile from the 18-19 April occupation of section A-4. Here the 0°C isotherm extends below 150 meters, but the minimum temperature was just less than -1.2°C . As was previously noted, conditions had changed dramatically across this section by the 9-10 May occupation (fig. 31). However, from the vertical temperature profile of the 13-14 May occupation of section A-3, (fig. 33) one can see that the core of the Labrador Current was present although restricted closer to continental slope. Temperatures less than -1.0°C were reported and the 0°C isotherm was found deeper than 200 meters. By mid-June surface water temperature along Section A-3 had increased, but a cold core with temperature less than -1.4°C was reported, and the 0°C isotherm extended to 250 meters (fig. 37).

Colder than normal conditions continued through July and August. Each year the Fisheries Research Board of Canada and Memorial University of Newfoundland conduct sections across the Labrador Current from southern Labrador to the Tail of the Bank. Through 2 August below average temperatures were recorded to as far south as Flemish Cap. Even toward the end of August, temperatures less than -1.7°C were recorded in the Labrador Current near the Tail of the Bank (Templeman, 1973). Thus the generally colder than average water conditions tended to reduce iceberg mortality through melting in 1972.

Air Temperatures

Melting of the subaerial portion of iceberg is directly related to the air temperature. From

December through June, air temperatures along the coast of Labrador and Newfoundland were below normal. Monthly average temperatures were most anomalous during the first part of this period as for instance in February when the average temperature was 4°C below normal (fig. 70). Temperatures approached normal as the year progressed, but even as late as May (fig. 71) temperatures were still 2°C below normal. Temperatures recorded in the spring at four stations along the eastern Canadian coast (Table 2) were typical of these low values. It was not until June that temperatures increased to above normal and were high enough to cause substantial melting. Another indication of these conditions are frost degree day accumulations. From seven of the reporting stations in western Greenland and eastern Canada, it can be seen that record accumulations existed in each case (U.S. NAV-OCEANO, 1972). Thus melting due to air temperature was also less than normal in 1972.

Precipitation

As has been noted by Wolford (1972) and other authors, iceberg deterioration is accelerated during the passing of a storm and its associated front. It was further concluded that this is caused by increased rains as well as the increased winds that accompany such storms. Wolford (1972) also presents an example demonstrating the huge heat transfer that can result from such rain. This rapid heat transfer causes increased melting as well as increased internal stresses that may cause the iceberg to calve.

It has been noted that the number of storms passing through the region of interest was greater than normal during the winter of 1971-1972 and the spring of 1972. However, due to the colder than normal conditions which prevailed, according to the weather log from October 1971 through July 1972 at the representative stations at Goose Bay, Newfoundland, Gander, Newfoundland, and St. John's (Torbay),

TABLE 2.—Monthly Average Air Temperature and Deviation From Average In $^{\circ}\text{C}$

| | APRIL | | MAY | | JUNE | |
|-------------|-------|------|------|------|------|------|
| | AVE | DEV | AVE | DEV | AVE | DEV |
| HOPEDALE | -9.5 | -4.4 | -1.1 | -2.8 | 5.0 | -2.2 |
| CARTWRIGHT | -7.2 | -4.4 | -0.6 | -3.9 | 7.8 | -1.1 |
| ST. ANTHONY | -4.4 | -3.3 | 0.0 | -3.3 | 6.7 | -1.1 |
| ST. JOHN'S | 0.0 | -1.1 | 5.0 | -0.6 | 15.0 | 4.4 |

Newfoundland (U.S. Dept. of Commerce, 1972) more snowfall and less rainfall than normal resulted. This snowfall resulted in a sharp increase in snow cover between 1970 and 1971 (Kukla and Kukla, 1974), and an increased snow cover also in 1972. The cold temperature of

snow prohibits iceberg melting and in addition a layer of snow on an iceberg will insulate it from solar radiation which will also help reduce melting. Thus during the 1972 ice season, precipitation in the form of snow caused less iceberg deterioration than normal.

CONCLUSIONS

The record number of icebergs drifting into the North Atlantic Ocean in 1972 was a result of all critical meteorological and oceanographic being favorable for such drift prior to and during the ice season. The single most important factor in this record year was the increased intensity of the Icelandic Low. This resulted in the favorable northwesterly winds carrying

colder than normal air temperatures, which in turn helped produce greater ice cover, lower sea temperatures, and less rainfall. Although the change in the Icelandic Low was the single most important change from the previous season it is noted that each condition discussed here is necessary for a record year. A change in any one would have caused a reduced iceberg count.

ACKNOWLEDGMENT

The author would like to recognize the efforts of the Commanding Officer, Officers, and Crew of the USCGC EVERGREEN whose cooperation and diligence were instrumental to the success of the oceanographic operations. In addition we would like to thank the following CG Oceanographic Unit personnel who participated in the collection of the data contained herein: HP-1-72--LT A. ROSEBROOK (Field Party Chief), LT M. TRAMMEL, MST1 S. HHSLOP, MST3 M. LOVE, HST3 J. SMALL, MST3 M. SHOUL, MST3 G. GREILICH, and MR. M. T. LEHDIGH (student trainee); HP-2-72—DR. T. WOLFORD (Field Party Chief), MR. L. HANNON, MST1 A. FILO, MST3 G. POLUBINSKY, MST3 G. ADAMS, MST3 J. SCHNEIDER; HP-3-72—LDCR R. ETTLE (Field Party Chief), LT A. LITTEKEN, MST2 B. PETERS, MST2 C. DUVALL, ET2 W. KRUG, MST3 A. BOEHM, MST3 J. SCHNEIDER.

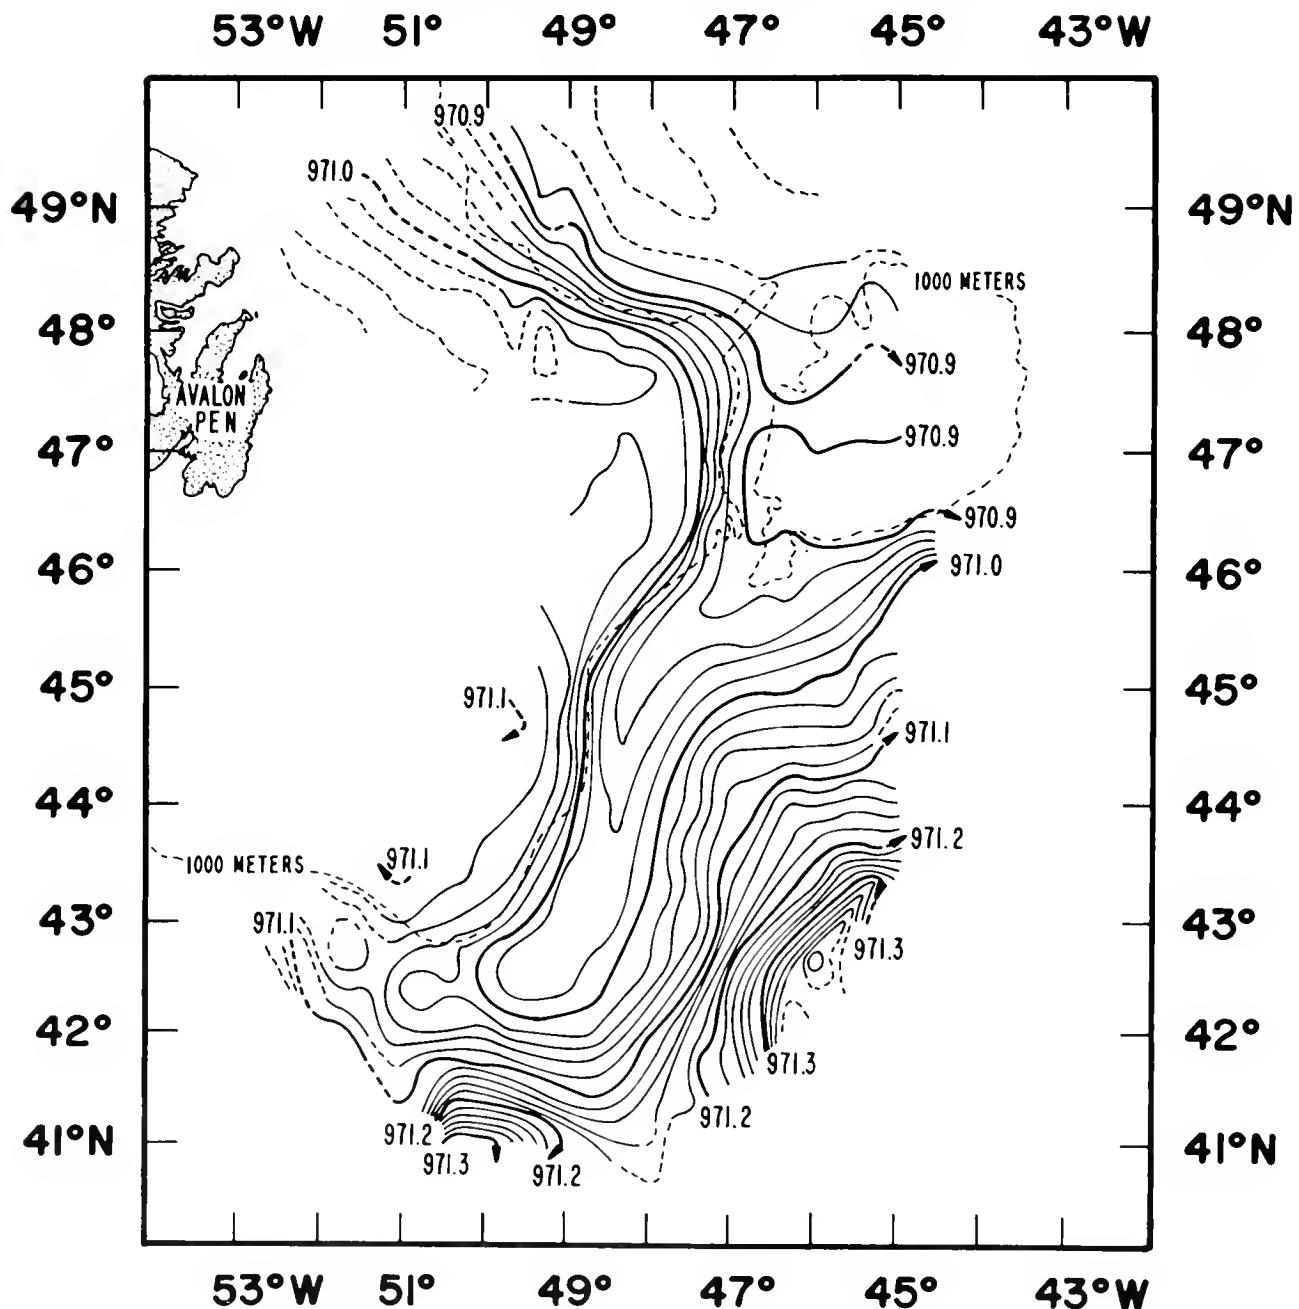

FIGURE 14. May monthly normal dynamic topography (dynamic meters of the sea surface relative to the 1,000 decibar surface). Contour interval is 2 dynamic centimeters.

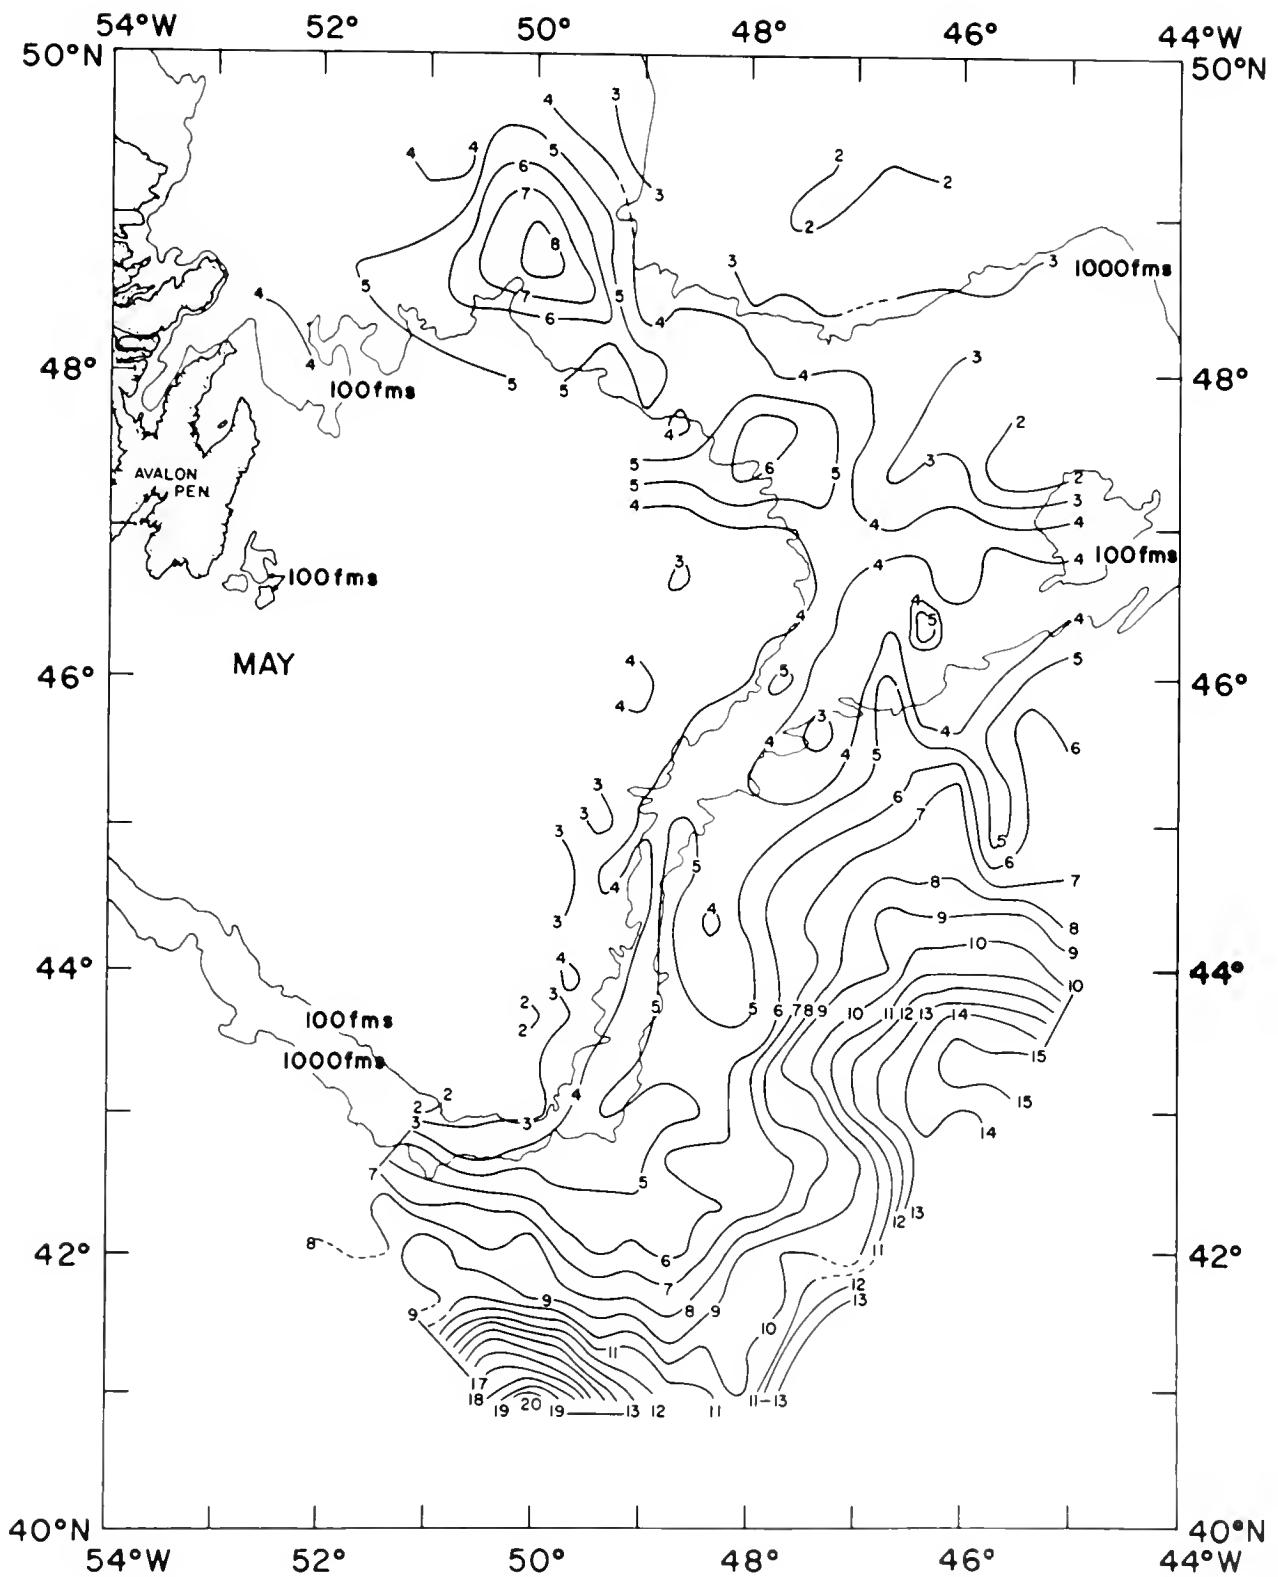

FIGURE 45. Field of standard deviation of dynamic height of the individual surveys from the May normal. Contour level is 1 dynamic centimeter.

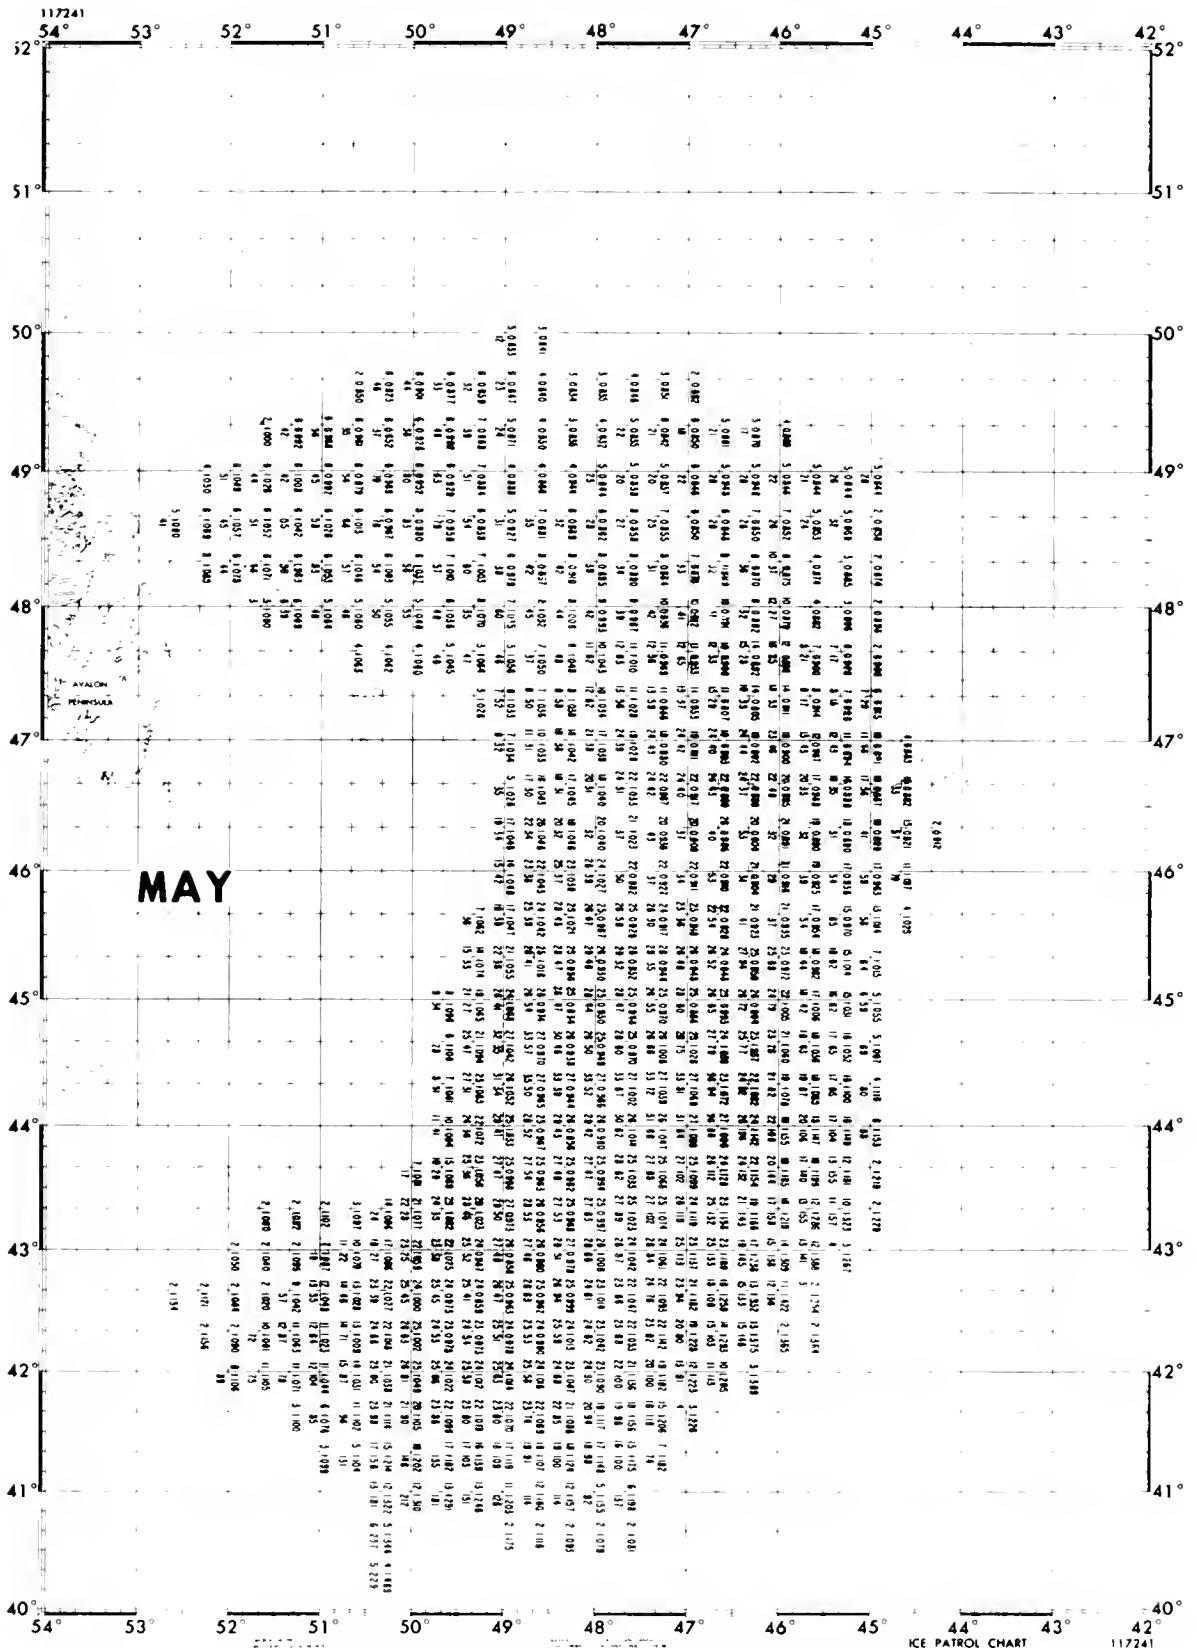

FIGURE 46. Numerical digest of data pertinent to the May normal dynamic topography.

MONTHLY NORMAL DYNAMIC TOPOGRAPHY FOR JUNE

53°W 51° 49° 47° 45° 43°W

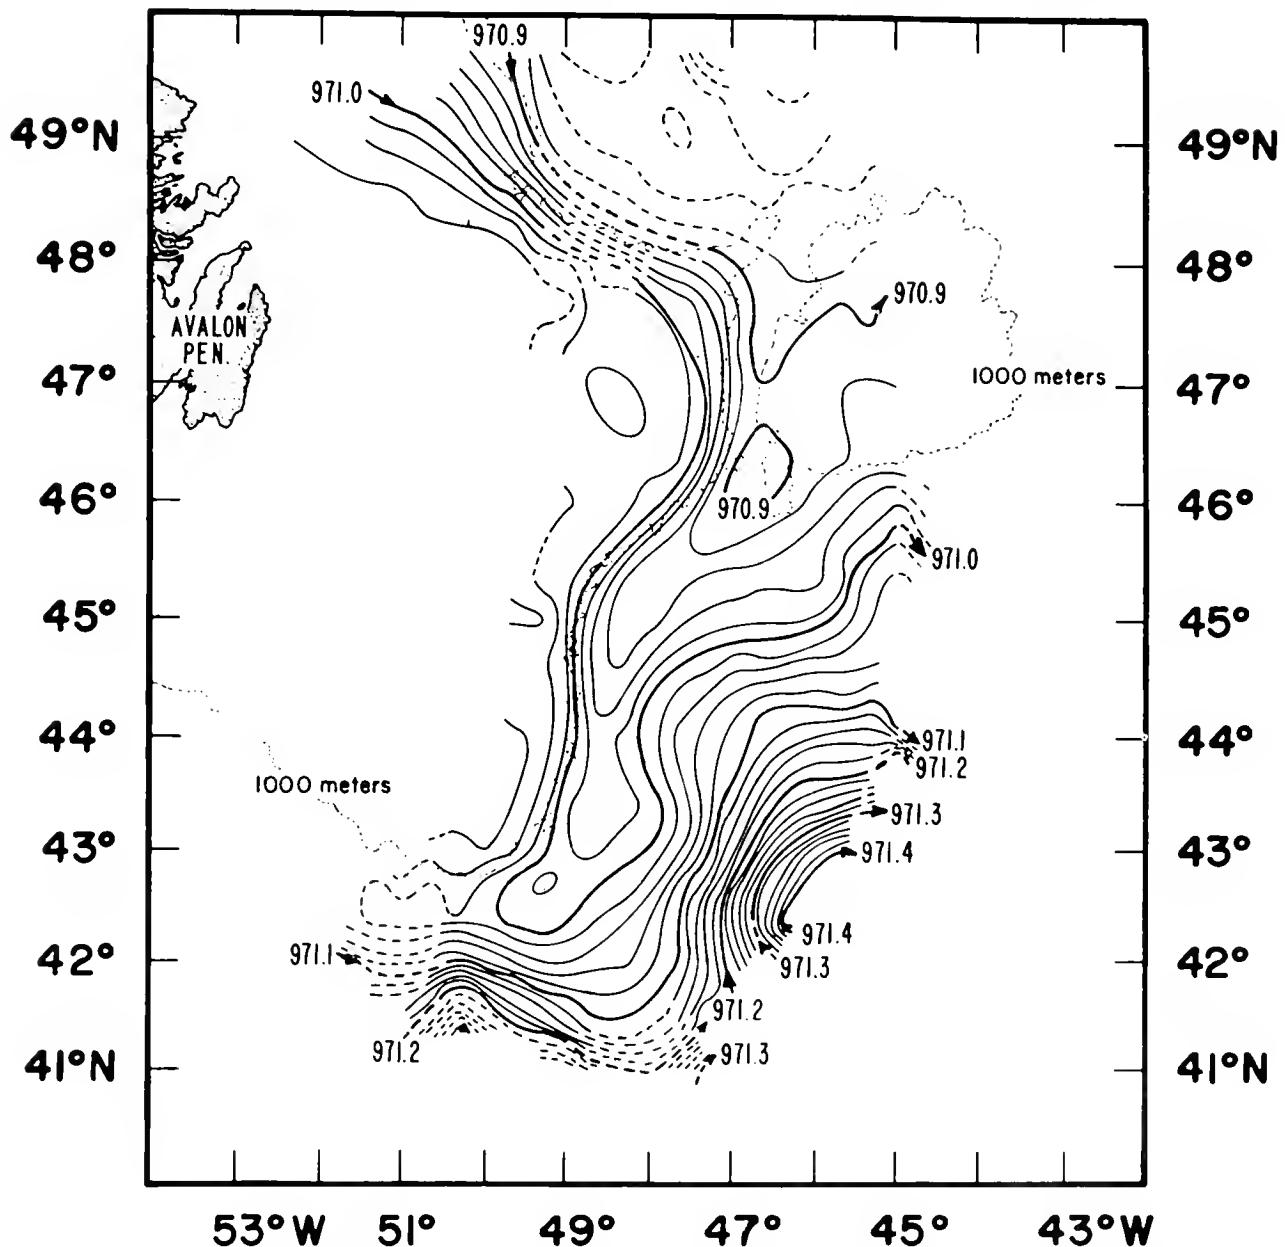

FIGURE 47. June monthly normal dynamic topography (dynamic meters) of the sea surface relative to the 1.000 decibar surface. Contour interval is 2 dynamic centimeters.

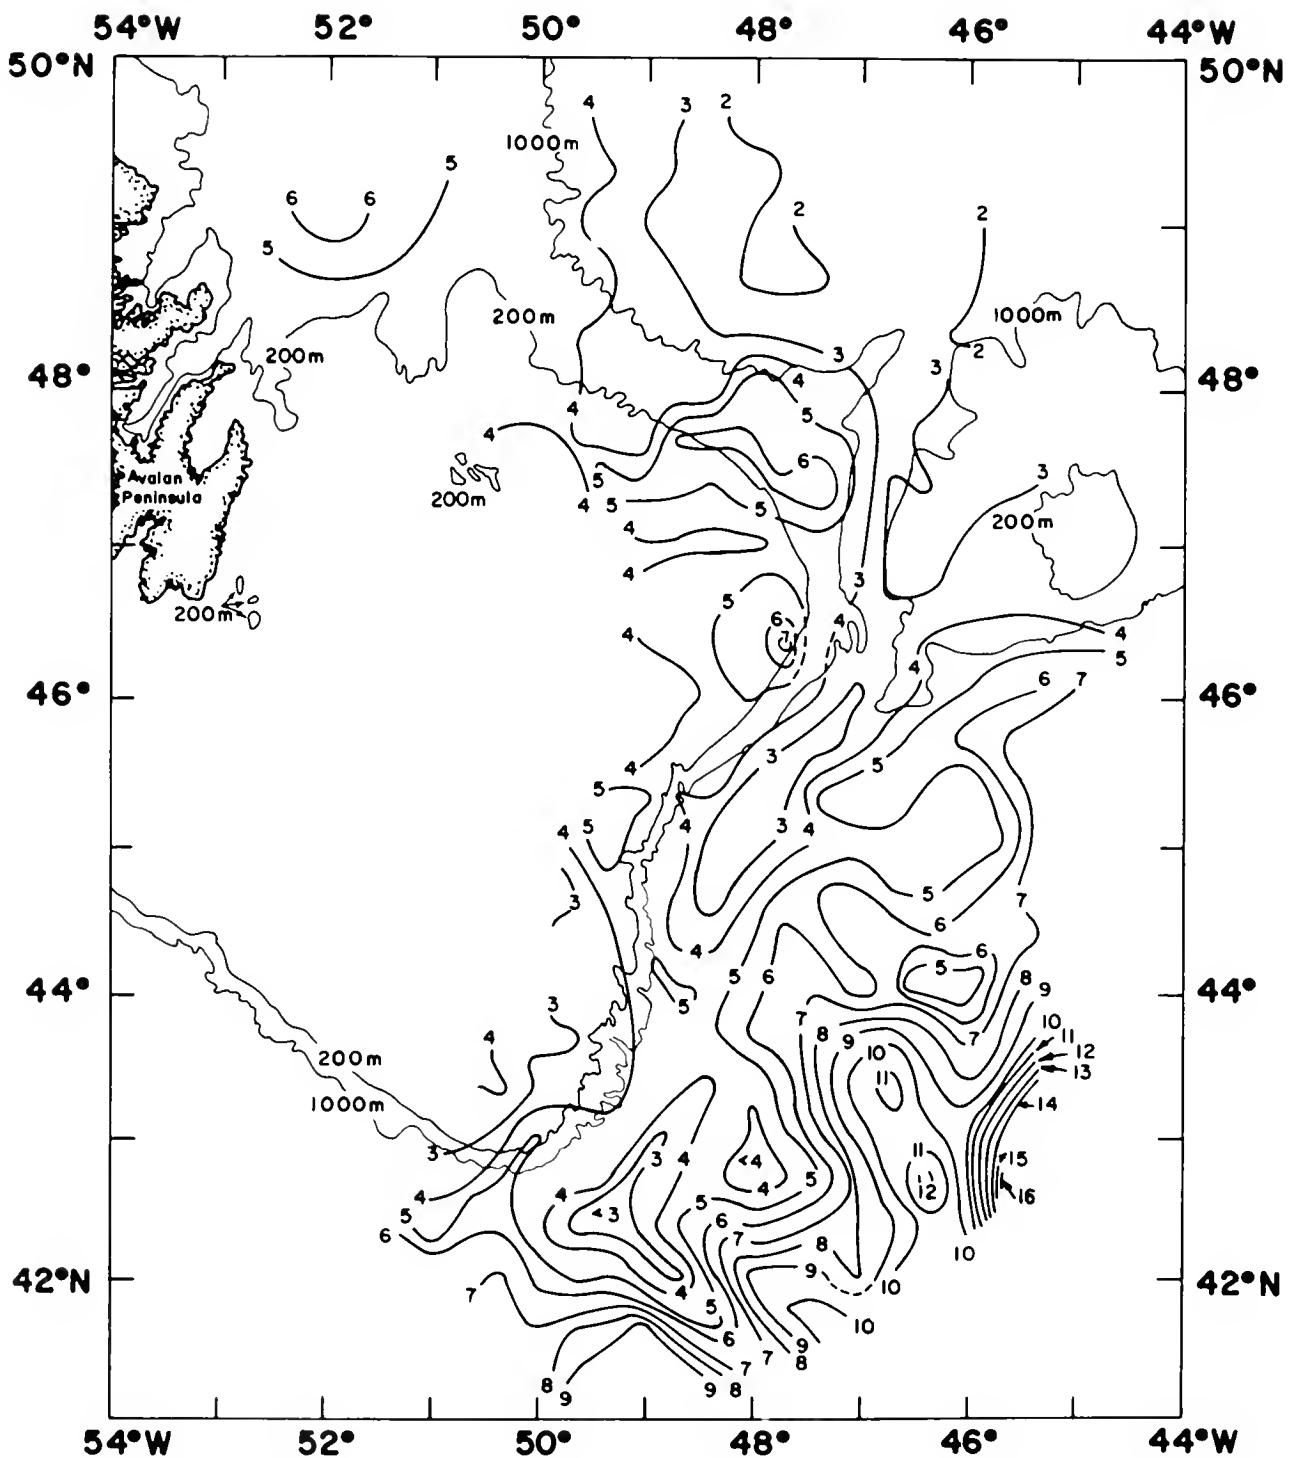

FIGURE 48. Field of standard deviation of dynamic height of the individual surveys from the June normal. Contour level is 1 dynamic centimeter.

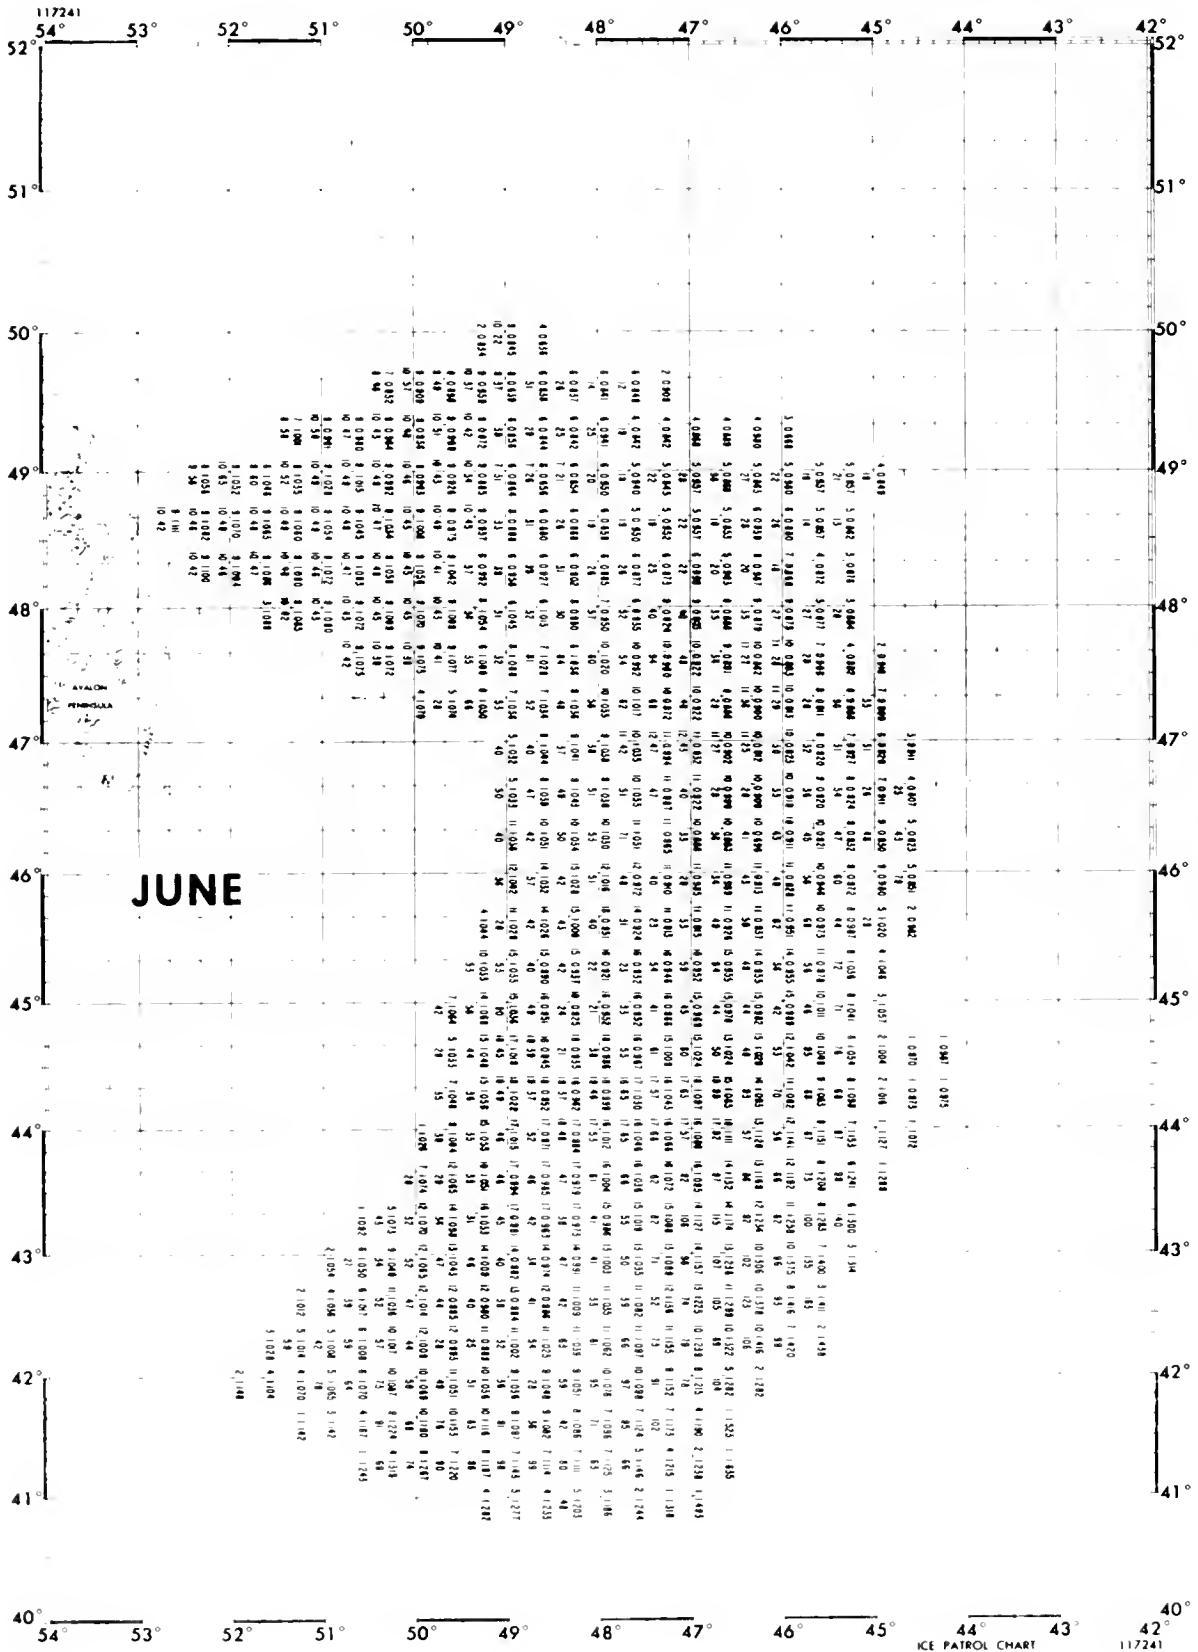

FIGURE 49. Numerical digest of data pertinent to the June normal dynamic topography.

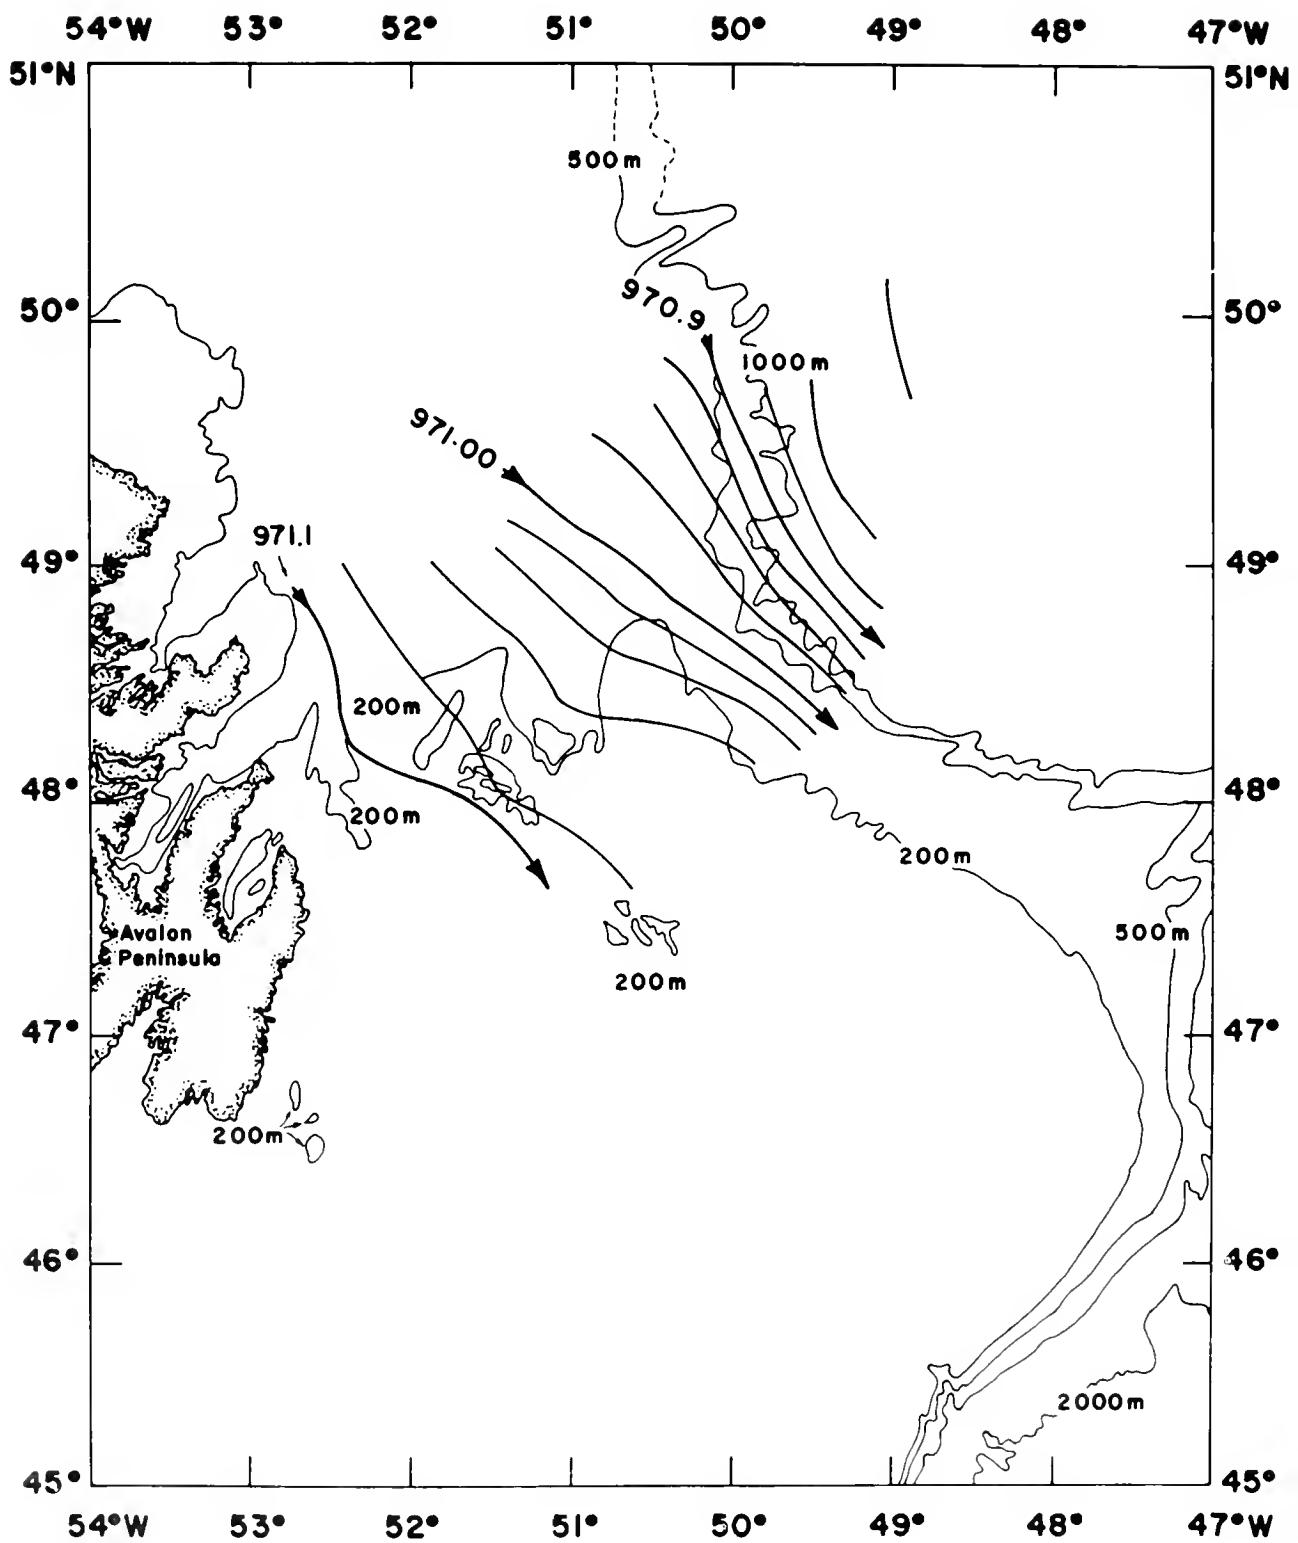

FIGURE 50. July monthly normal dynamic topography (dynamic meters) of the sea surface relative to the 1,000 decibar surface. Contour interval is 2 dynamic centimeters.

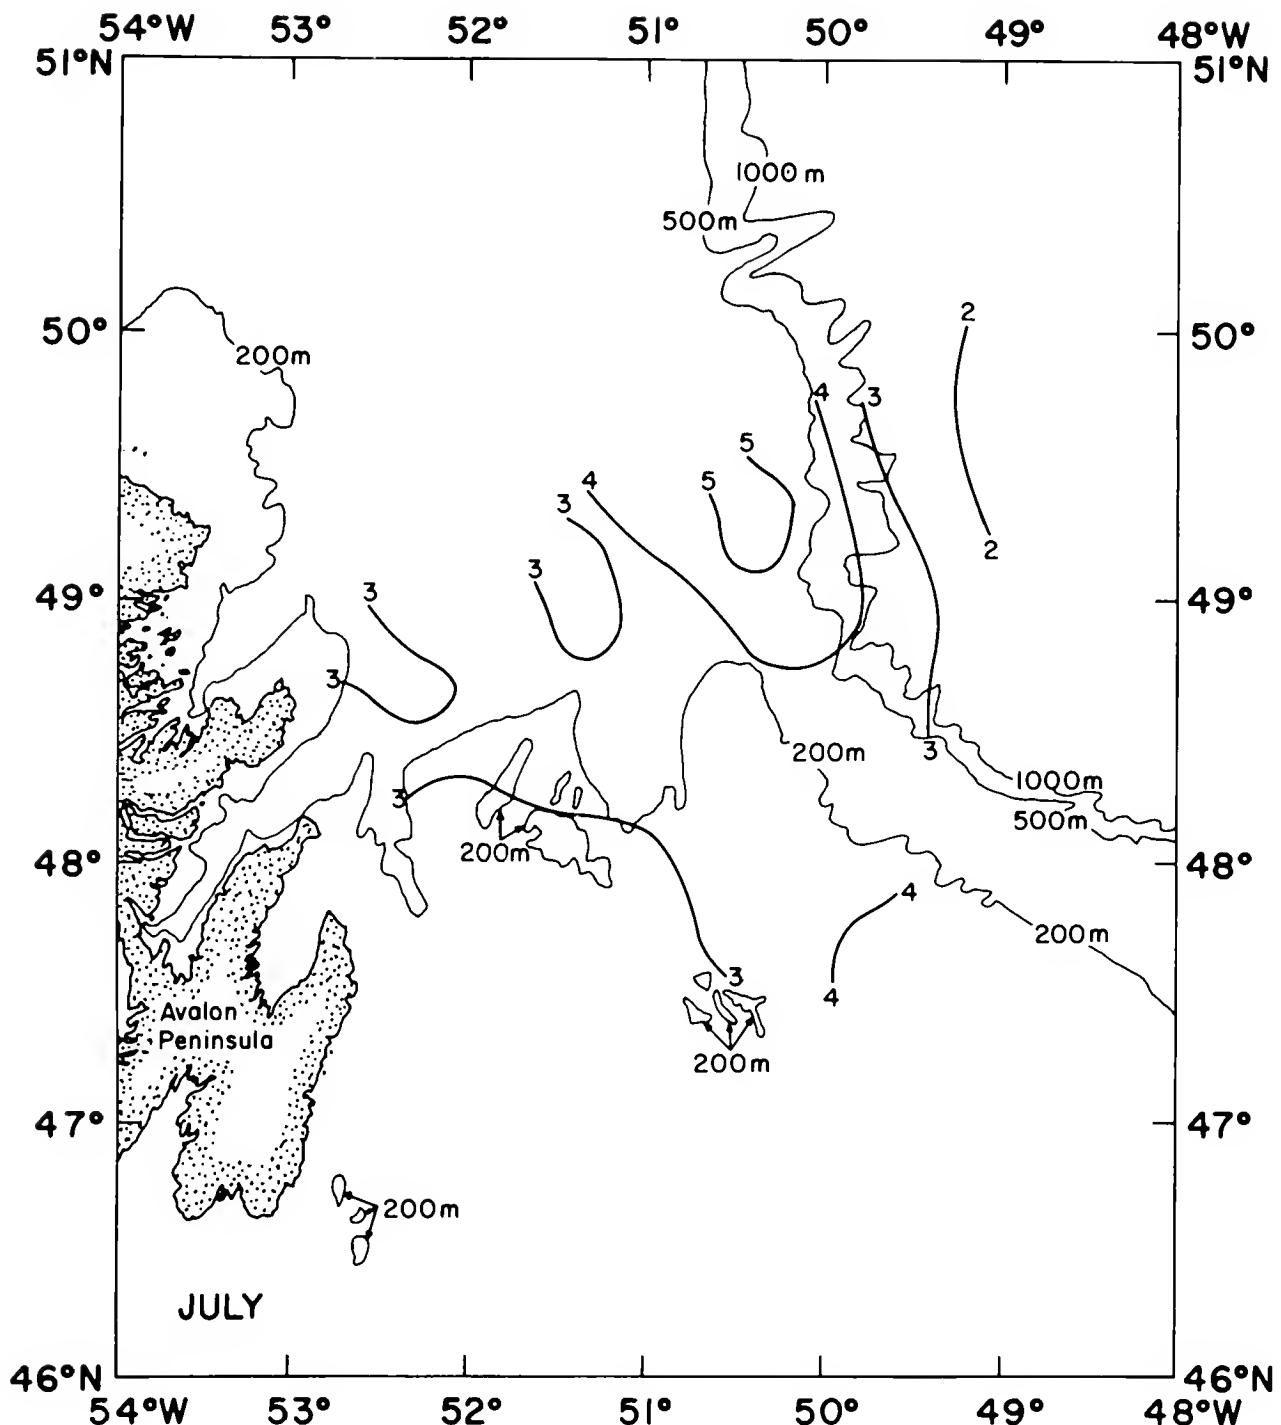

FIGURE 51. Field of standard deviation of dynamic height of the individual surveys from the July normal. Contour level is 1 dynamic centimeter.

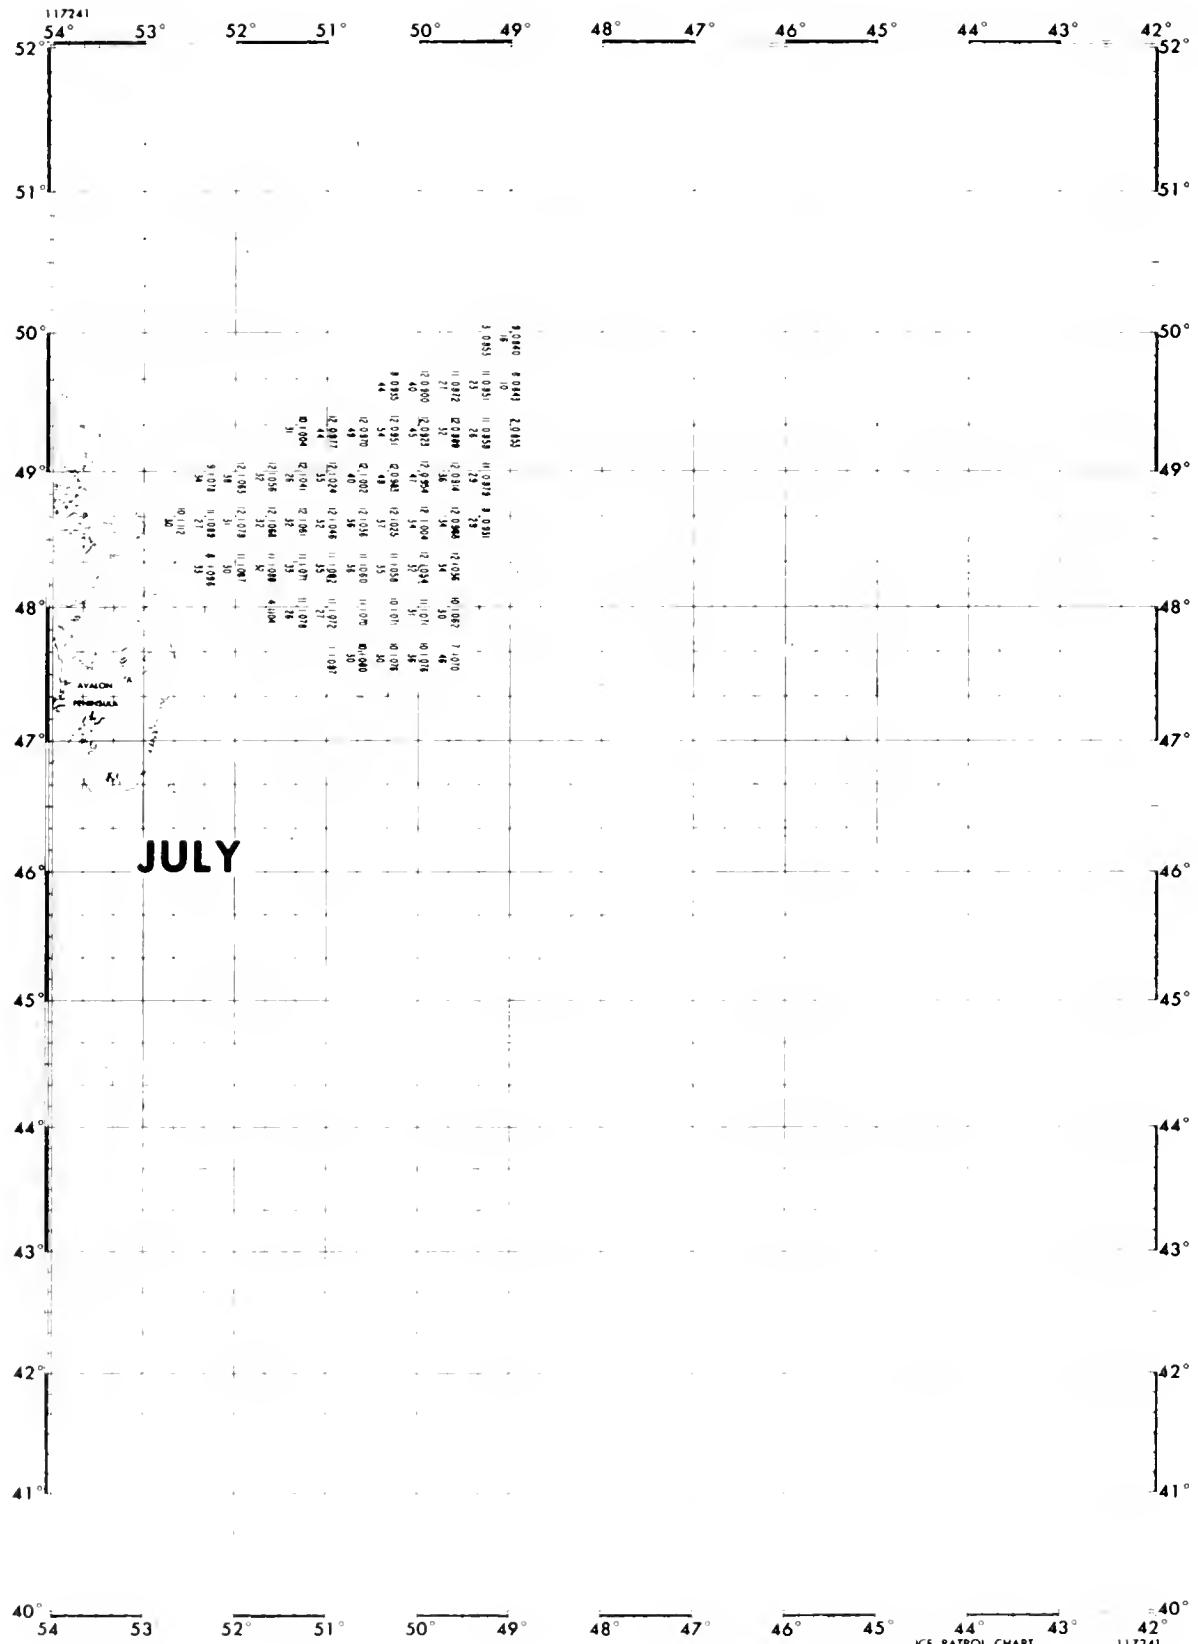

FIGURE 52. Numerical digest of data pertinent to the July normal dynamic topography.

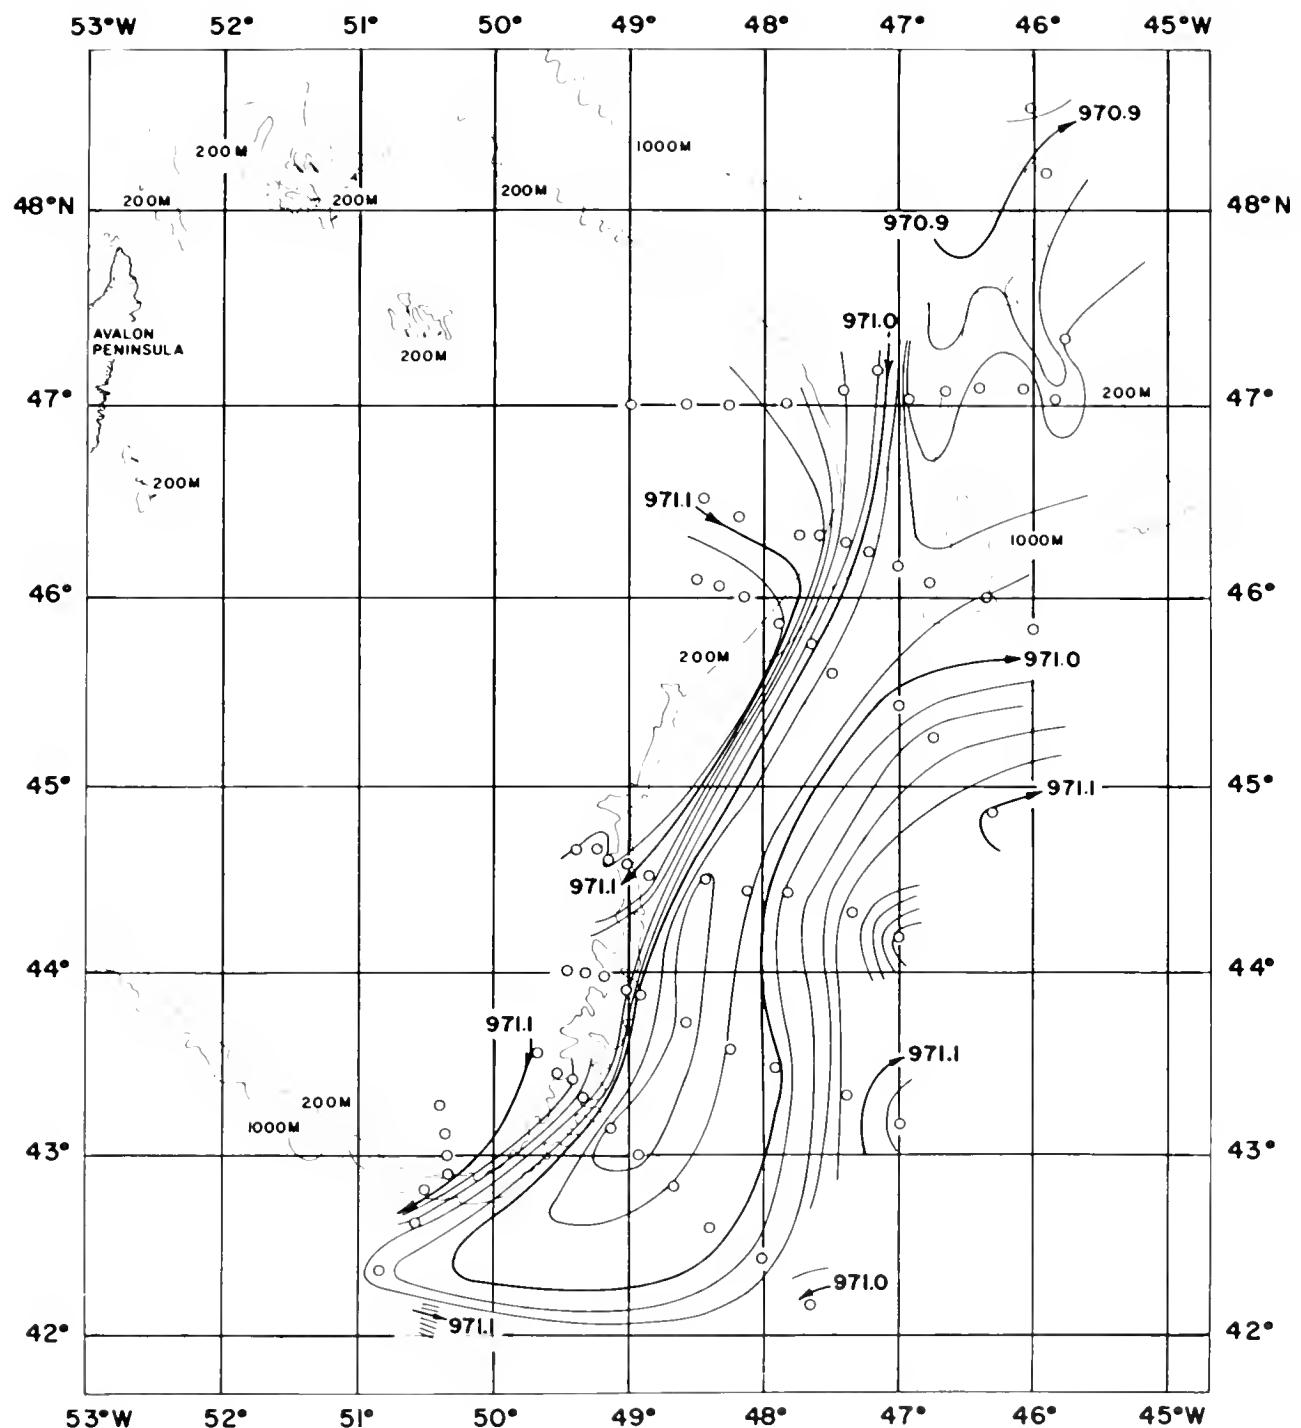

FIGURE 53. Sea surface dynamic topography (dynamic meters) relative to the 1,000 decibar level, CGC EVERGREEN 7 18 April 1972. Contour level is 2 dynamic centimeters.

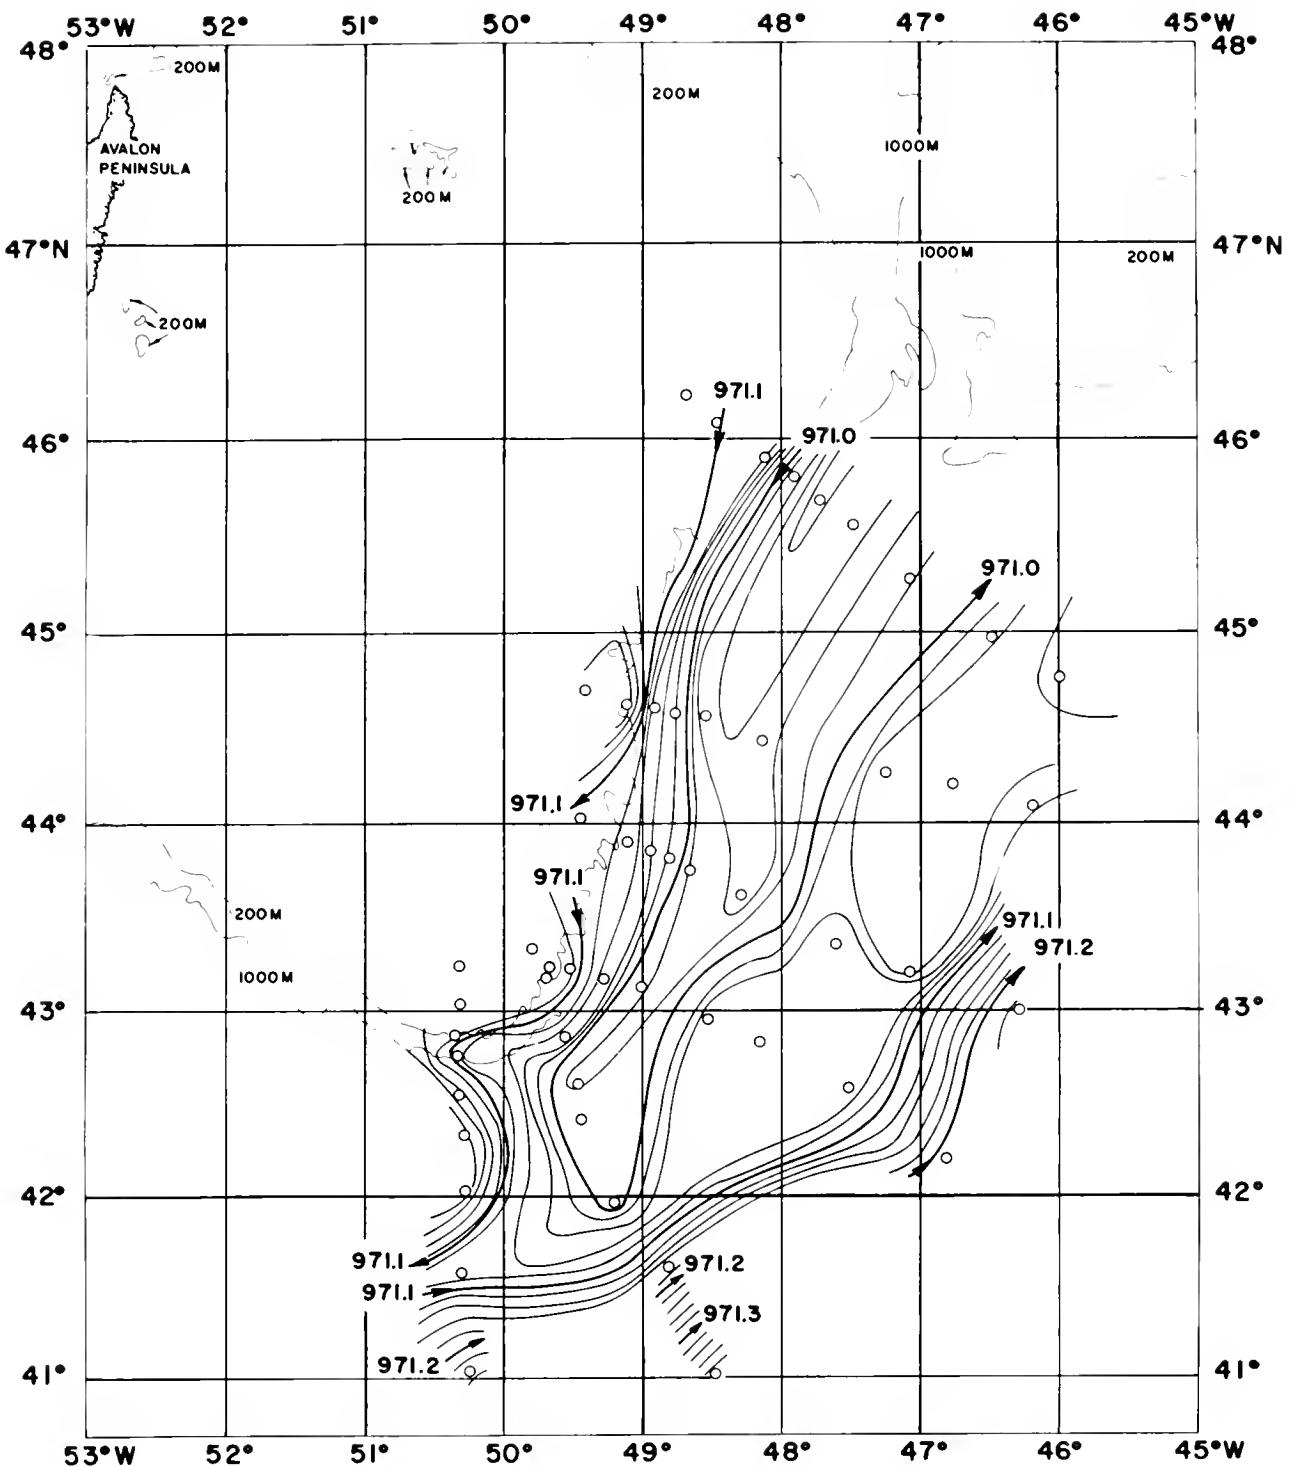

FIGURE 54. Sea surface dynamic topography (dynamic meters) relative to the 1,000 decibar level, CGC EVERGREEN 9-14 May 1972. Contour level is 2 dynamic centimeters.

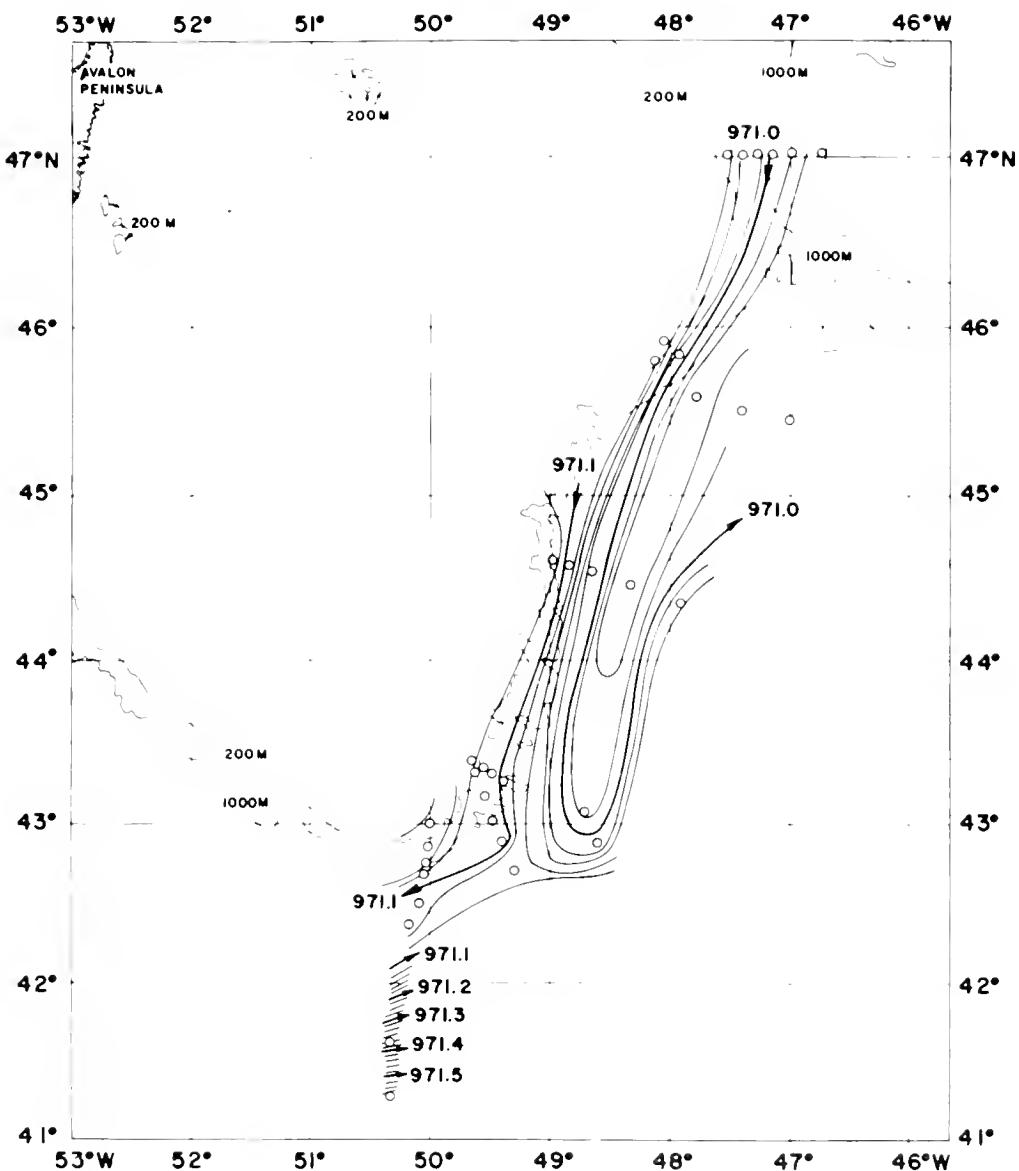

FIGURE 55. Sea surface dynamic topography (dynamic meters) relative to the 1,000 decibar level, CGC EVERGREEN 7-18 June 1972. Contour level is 2 dynamic centimeters.

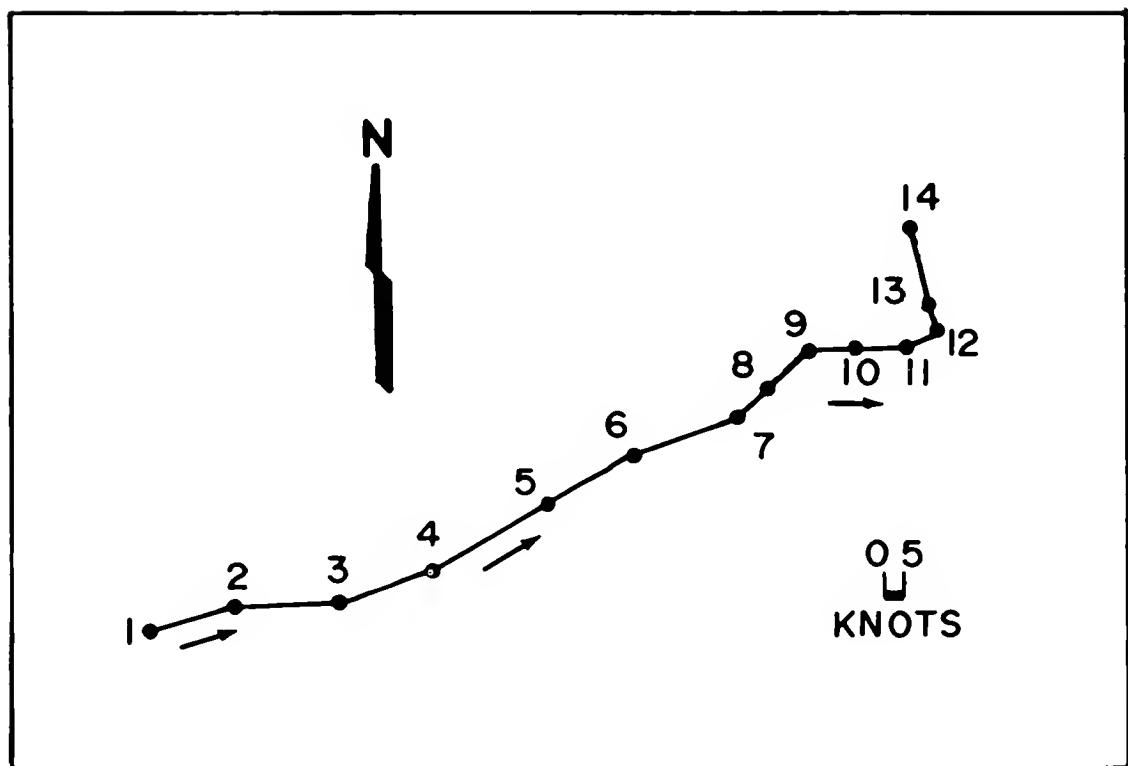

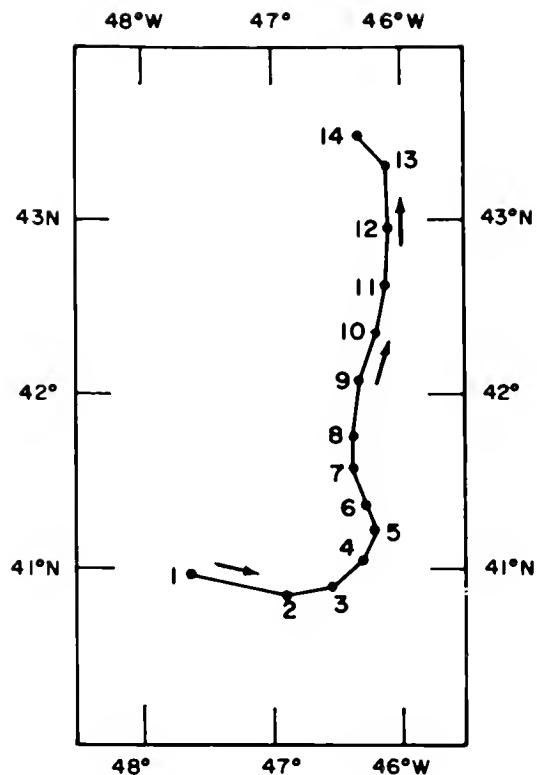

FIGURE 56. a. Drift of iceberg tracked from 5 to 11 May 1972 (Observations commenced 0500Z 5 May sample interval 12 hours). b. Progressive vector diagram of winds in vicinity of study iceberg (Observations commenced 0000Z 5 May sample interval 12 hours).

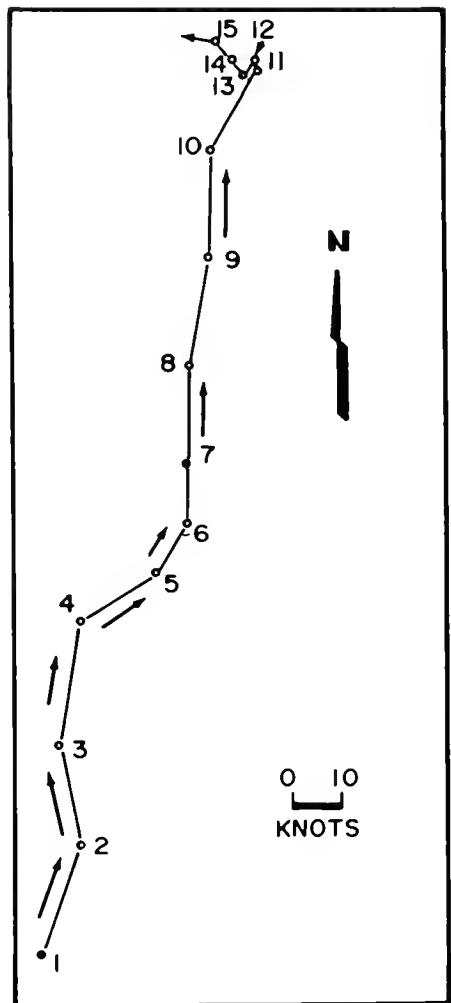

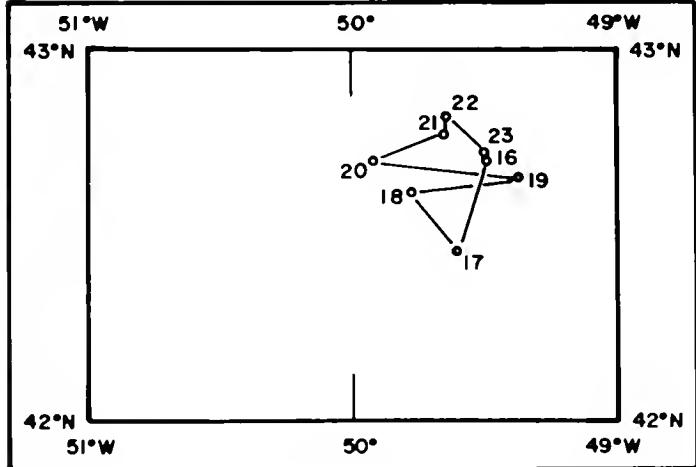

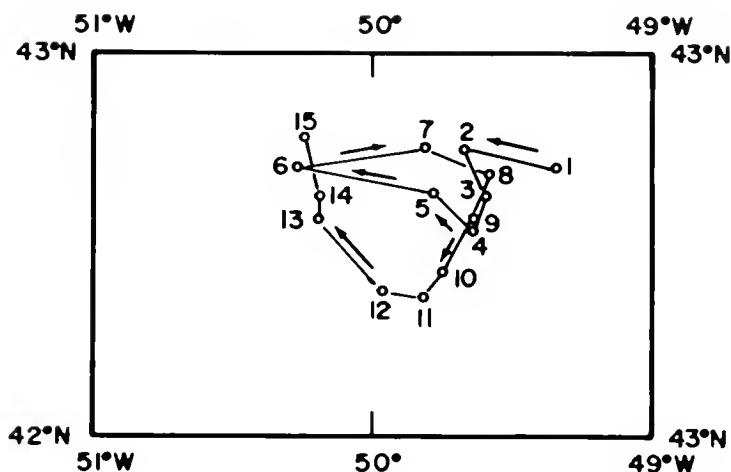

FIGURE 57. a. Drift of iceberg tracked from 8 to 15 June 1972 (Observations commenced 1200Z 8 June—sample interval 12 hours). b. Drift of iceberg tracked from 9 to 13 June 1972 (Observations commenced 1200Z 9 June—sample interval 12 hours). c. Progressive vector diagram of winds in the vicinity of the study icebergs (Observations commenced 1200Z 8 June—sample interval 12 hours).

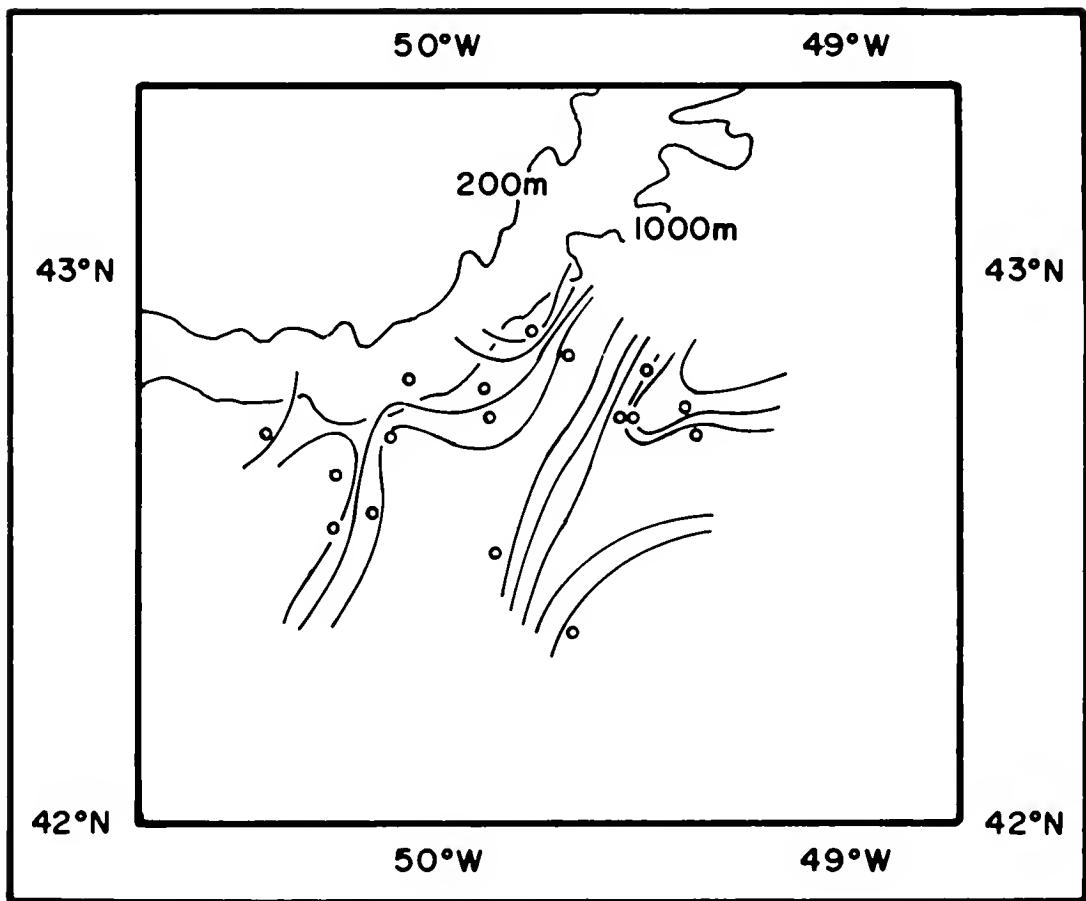

FIGURE 58. Sea surface dynamic topography (dynamic meters) relative to the 1,000 decibar level, CGC EVERGREEN 8-15 June 1972. Contour level is 2 dynamic centimeters.

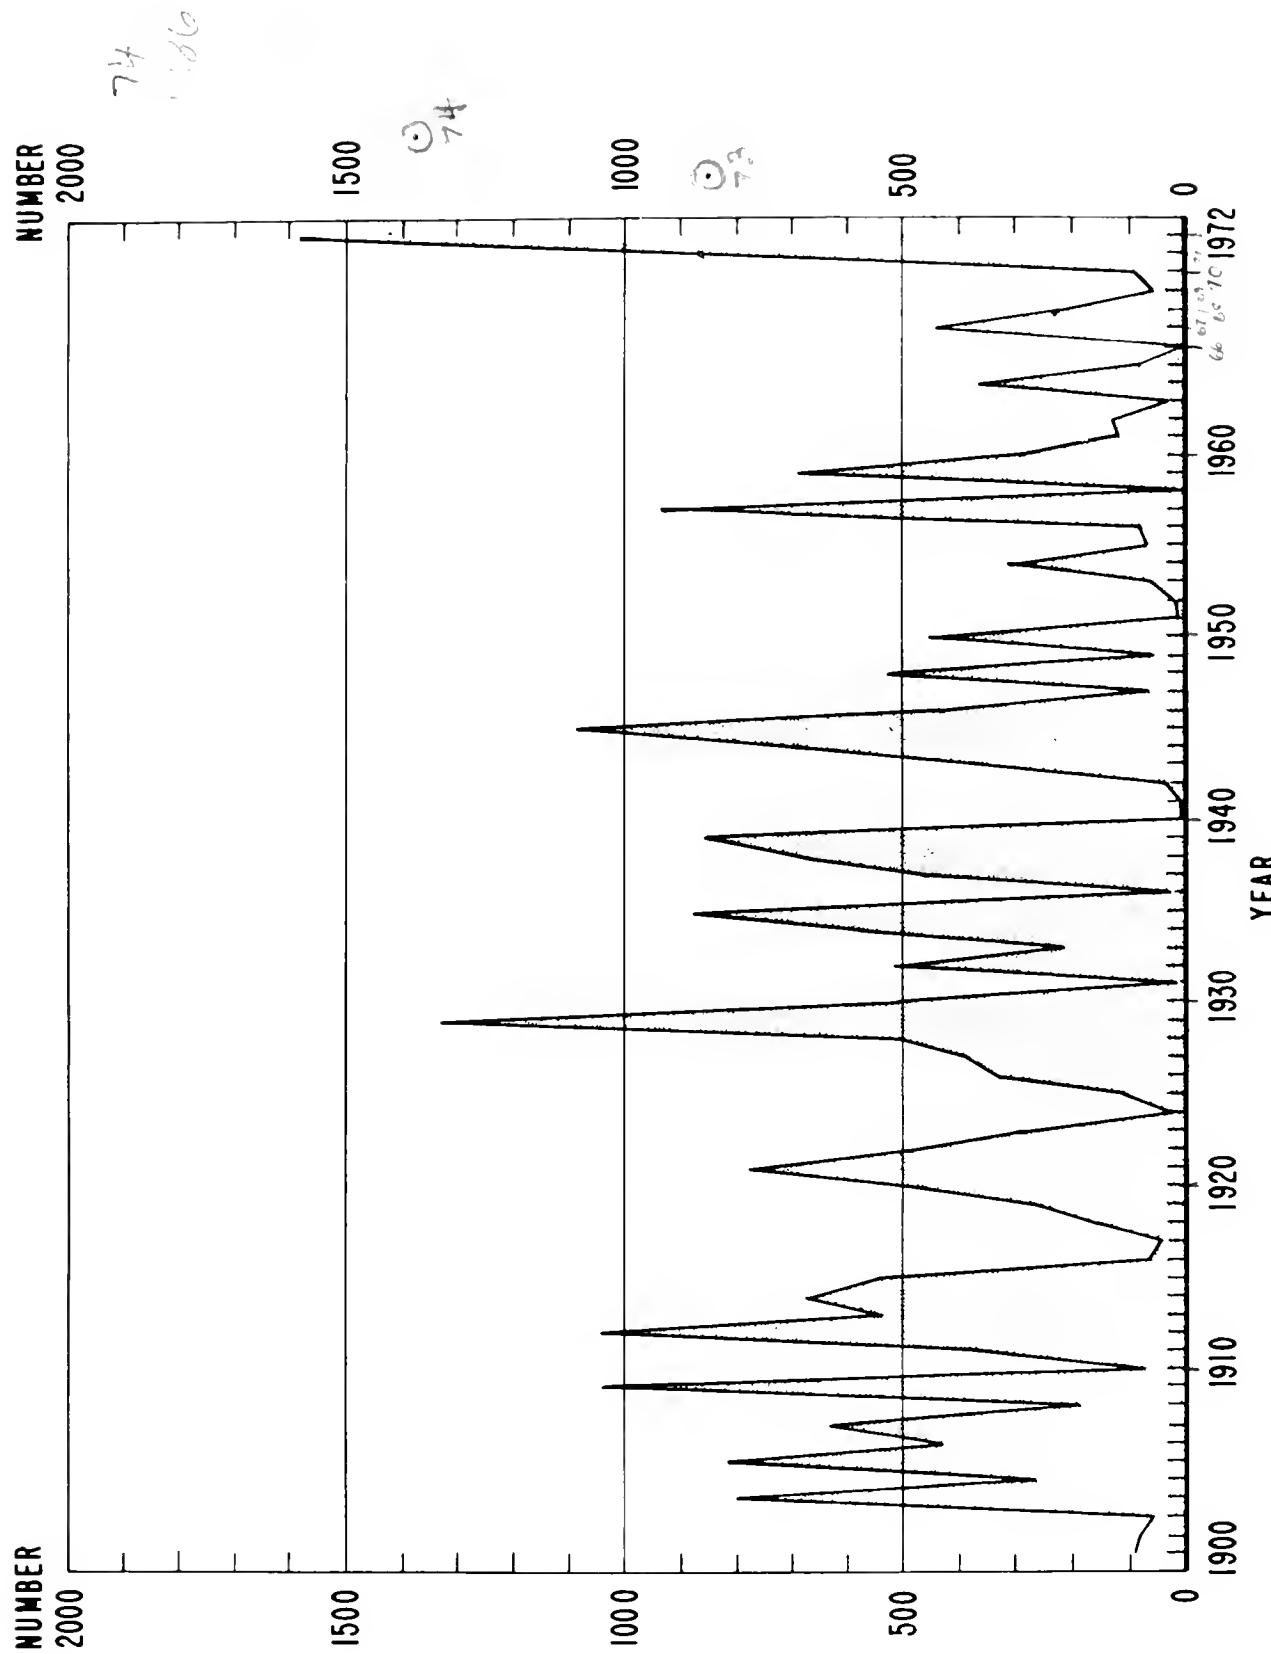

FIGURE 59. Number of icebergs per year which drifted south of 48°N (1900–1972).

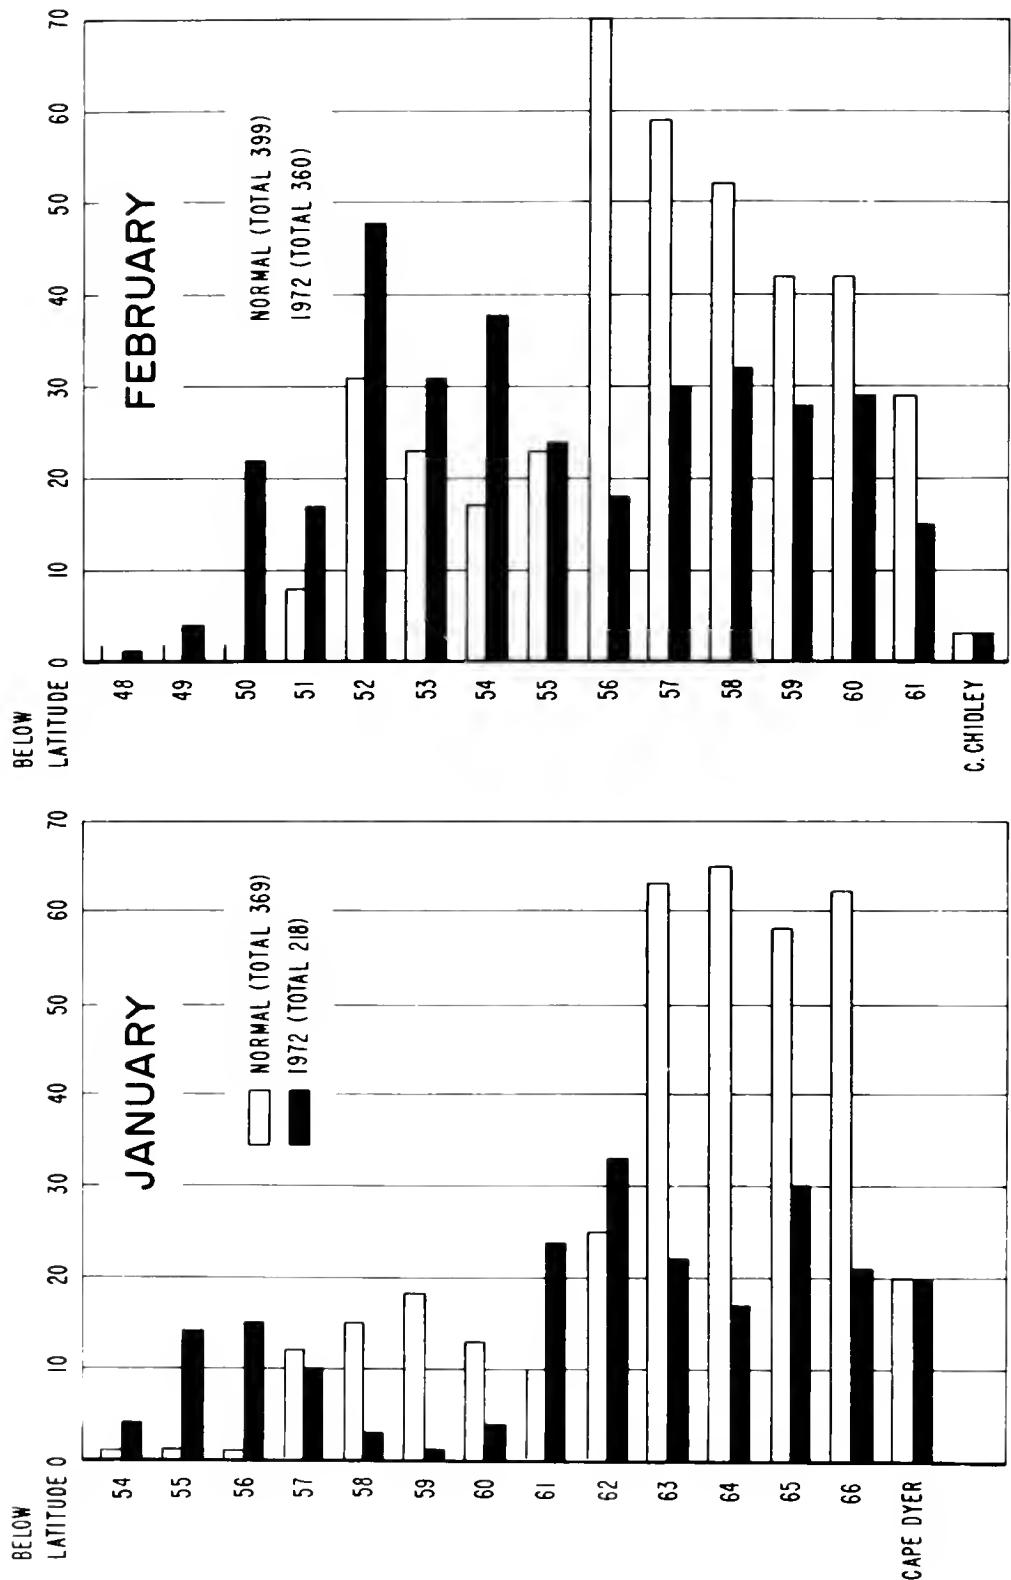

FIGURE 60. Icebergs sighted by January 1972 and February 1972 preseason reconnaissance flights.

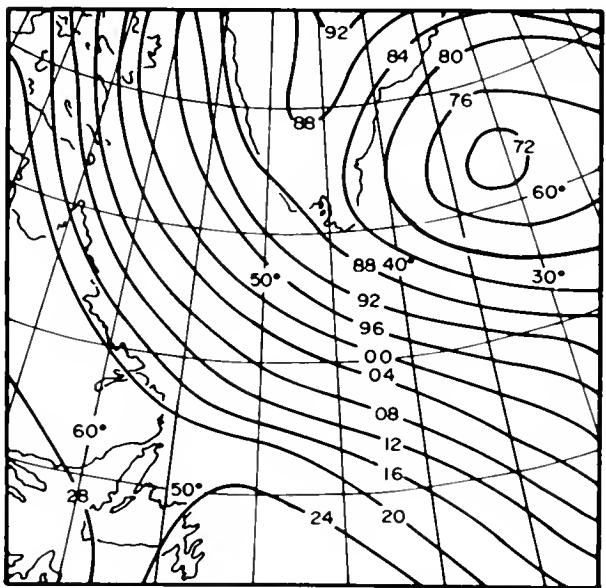

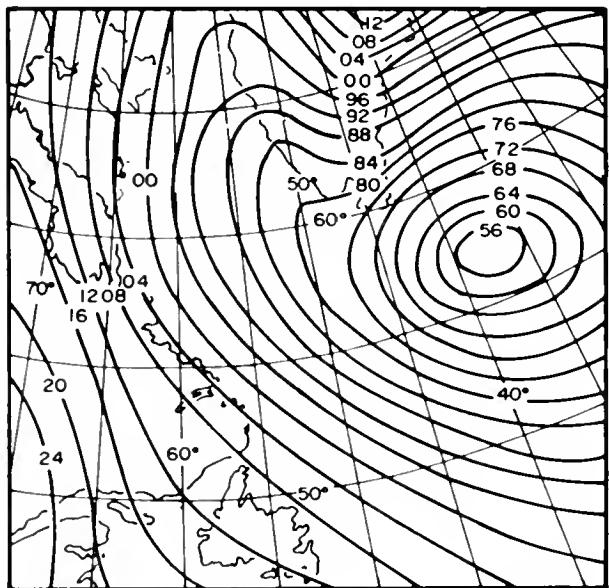

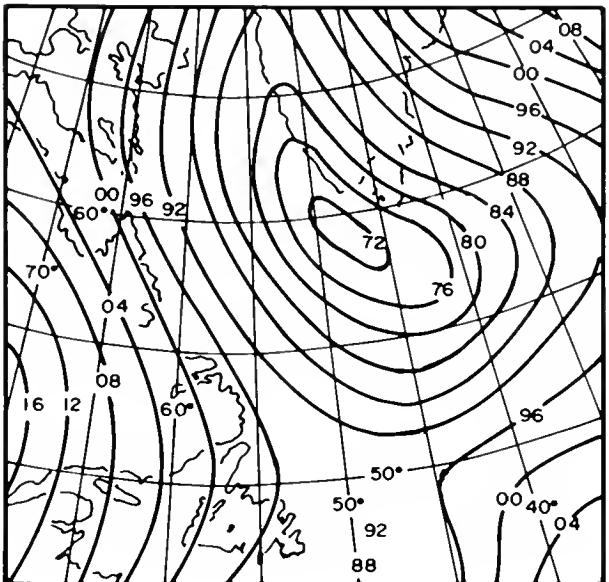

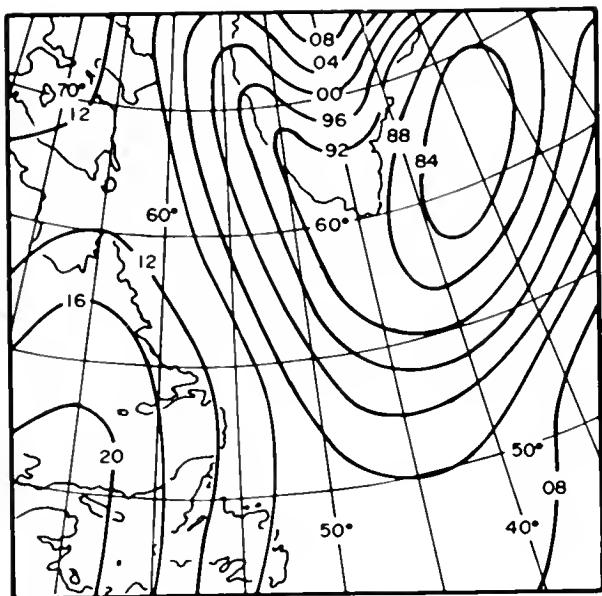

FIGURE 61. Four low pressure systems typical of conditions which existed during the winter of 1971-1972. a. 3 December 1971. b. 6 January 1972. c. 2 February 1972. d. 3 March 1972.
Contour interval is 4 decibars.

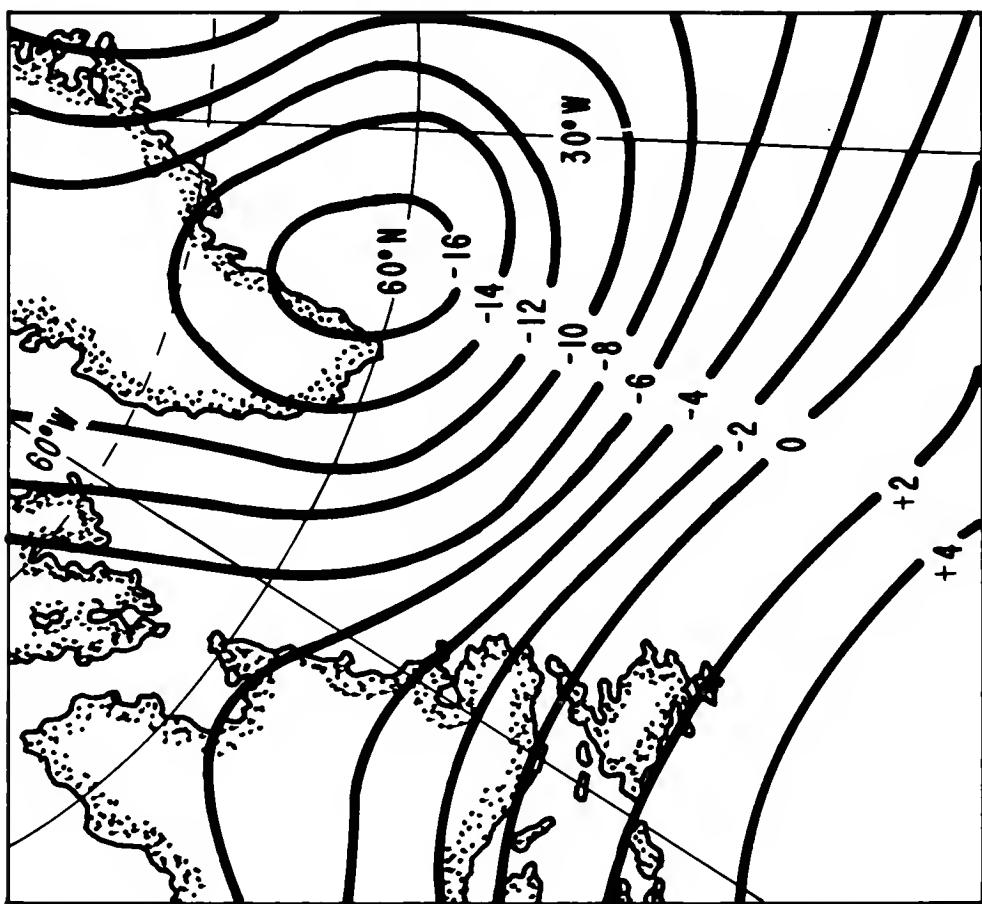

FIGURE 62. Surface pressure anomaly for January 1972 (after Sanderson, 1972). Contour interval 2 decibars.

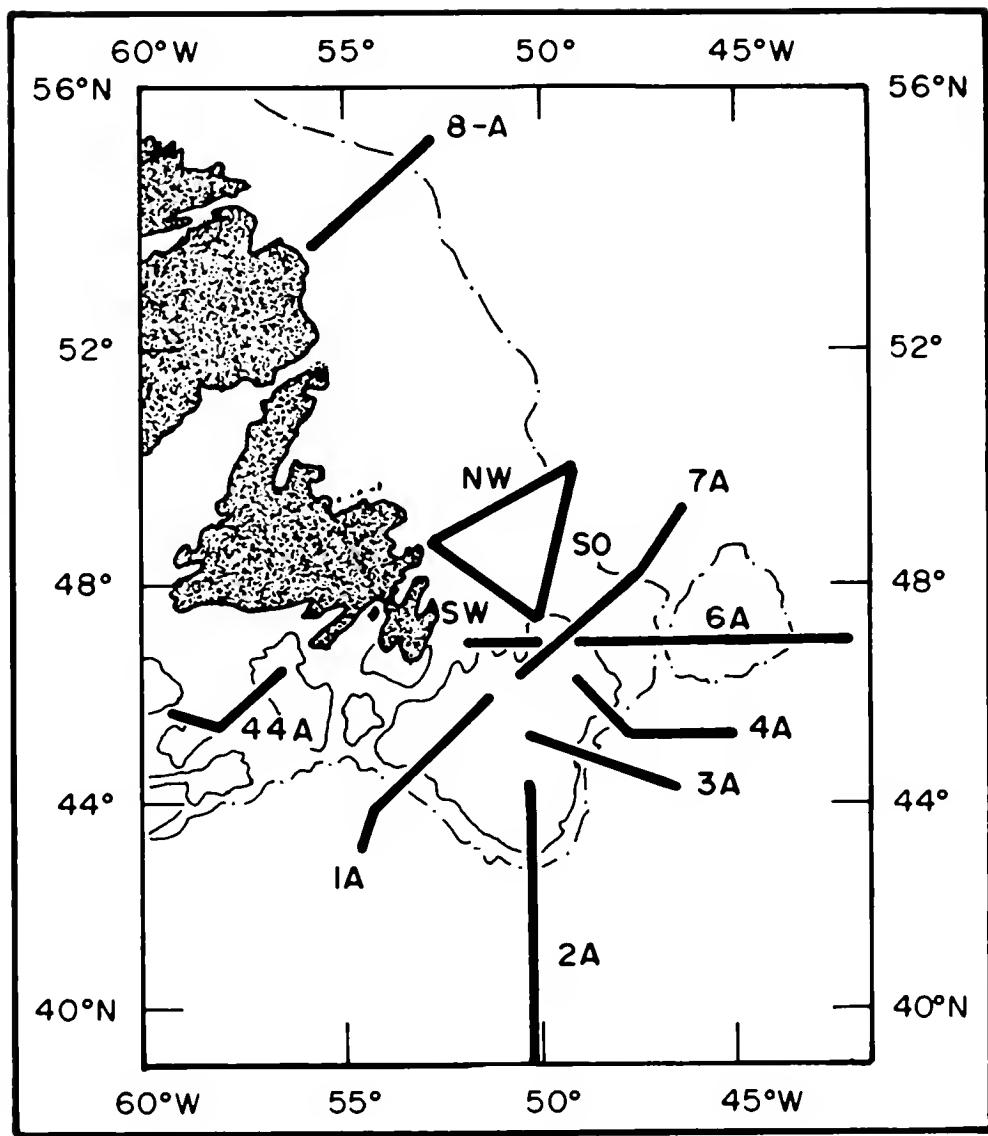

FIGURE 63. Standard Russian oceanographic sections near Newfoundland (after Burmakin).

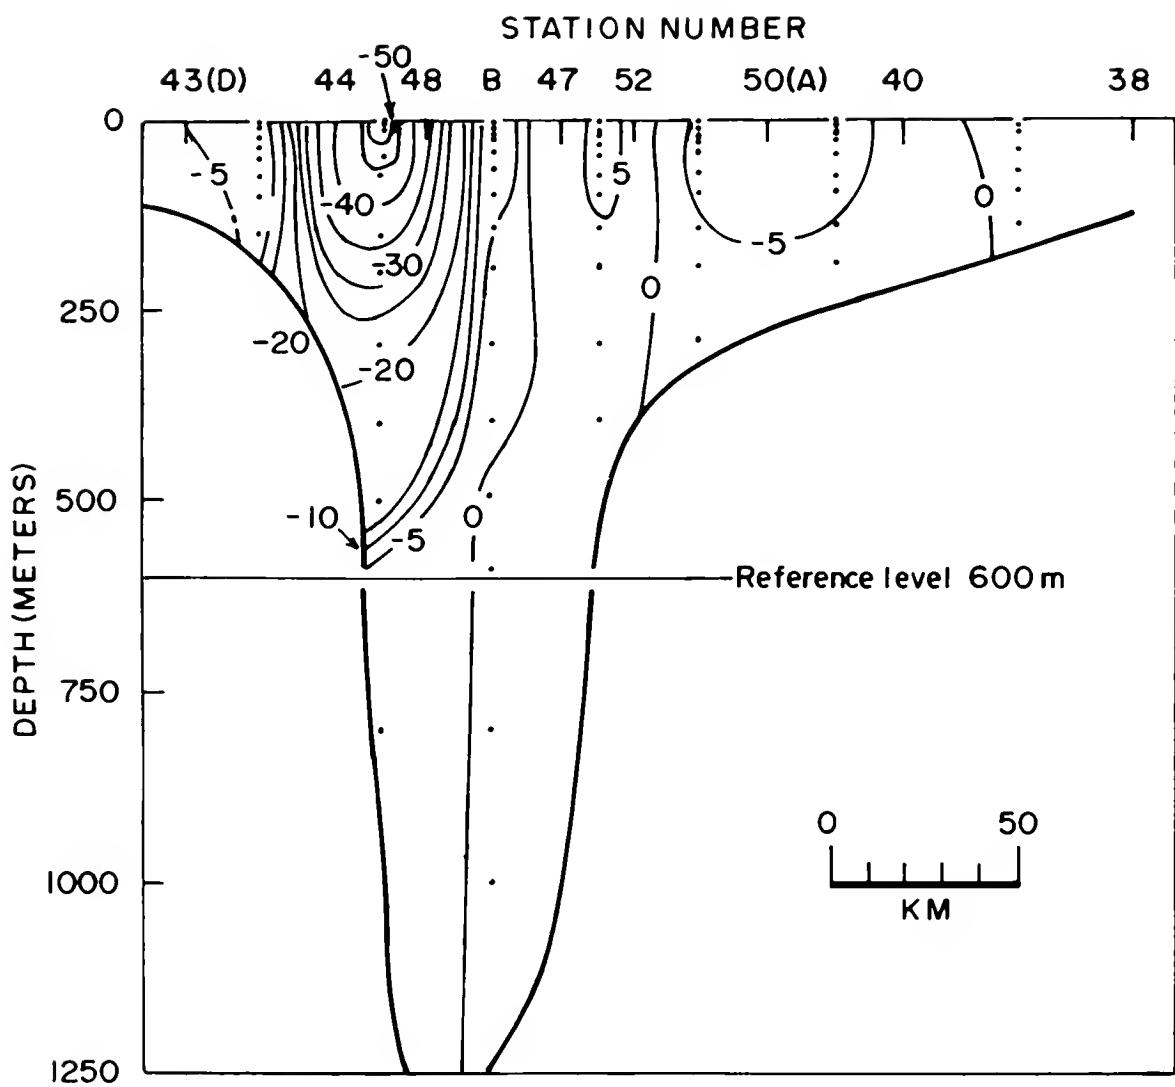

FIGURE 64. Vertical current (cm/sec) profile for the 17-18 April 1972 occupation of the Grand Banks-Flemish Cap Section (after Hill et al.). Positive numbers represent northerly flow.

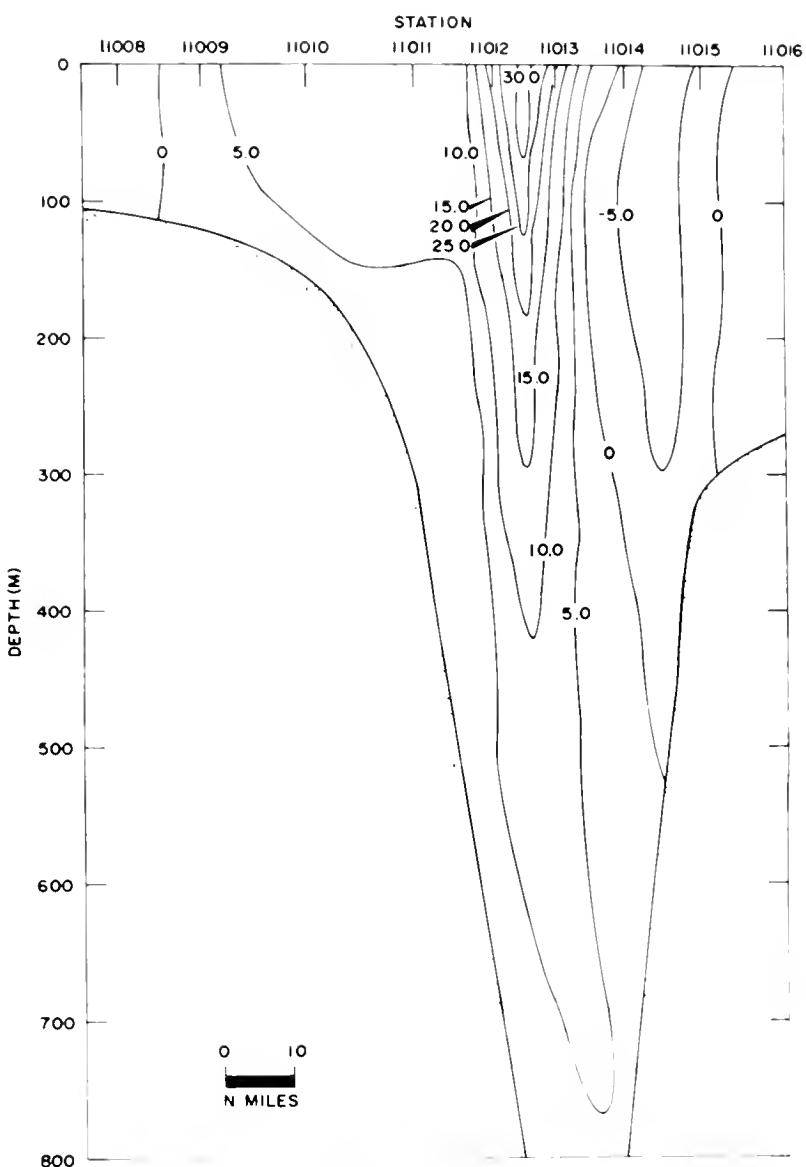

FIGURE 65. Vertical current (cm/sec) profile for the 7-9 April 1972 occupation of section A2.
Positive numbers represent southerly flow.

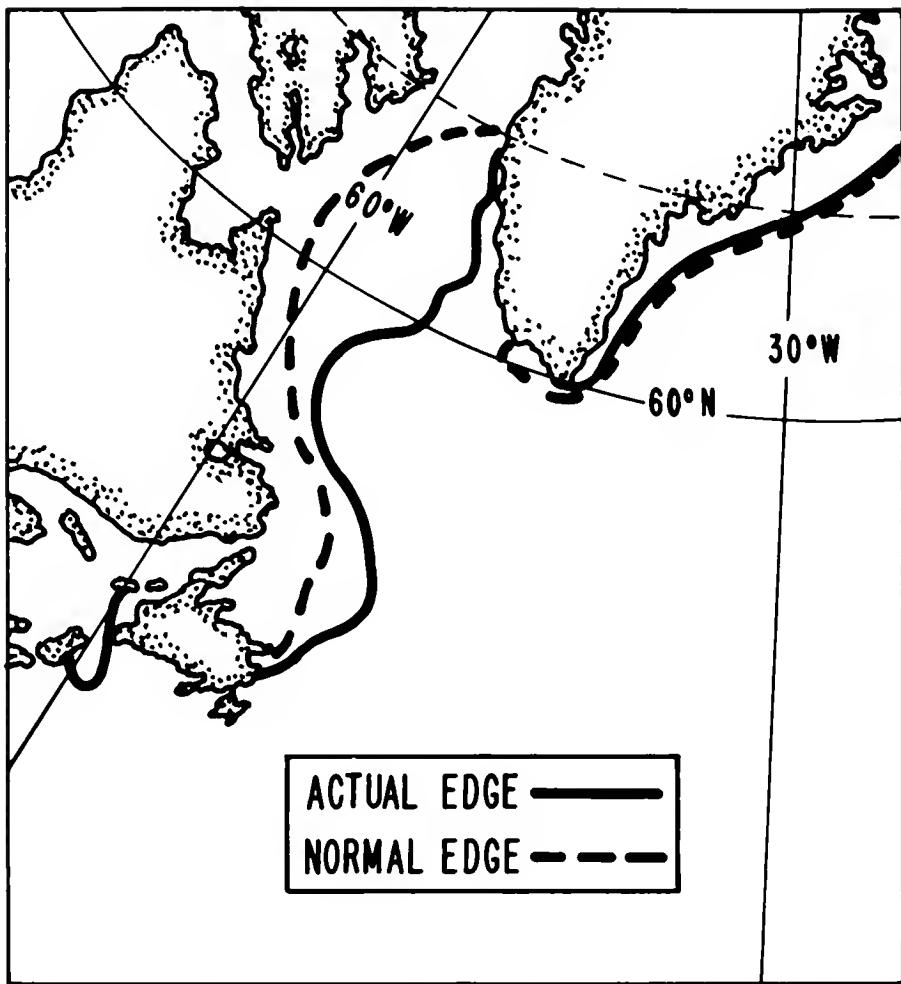

FIGURE 66. Normal sea ice edge compared with January 1972 sea ice edge
(after Sanderson, 1972 b).

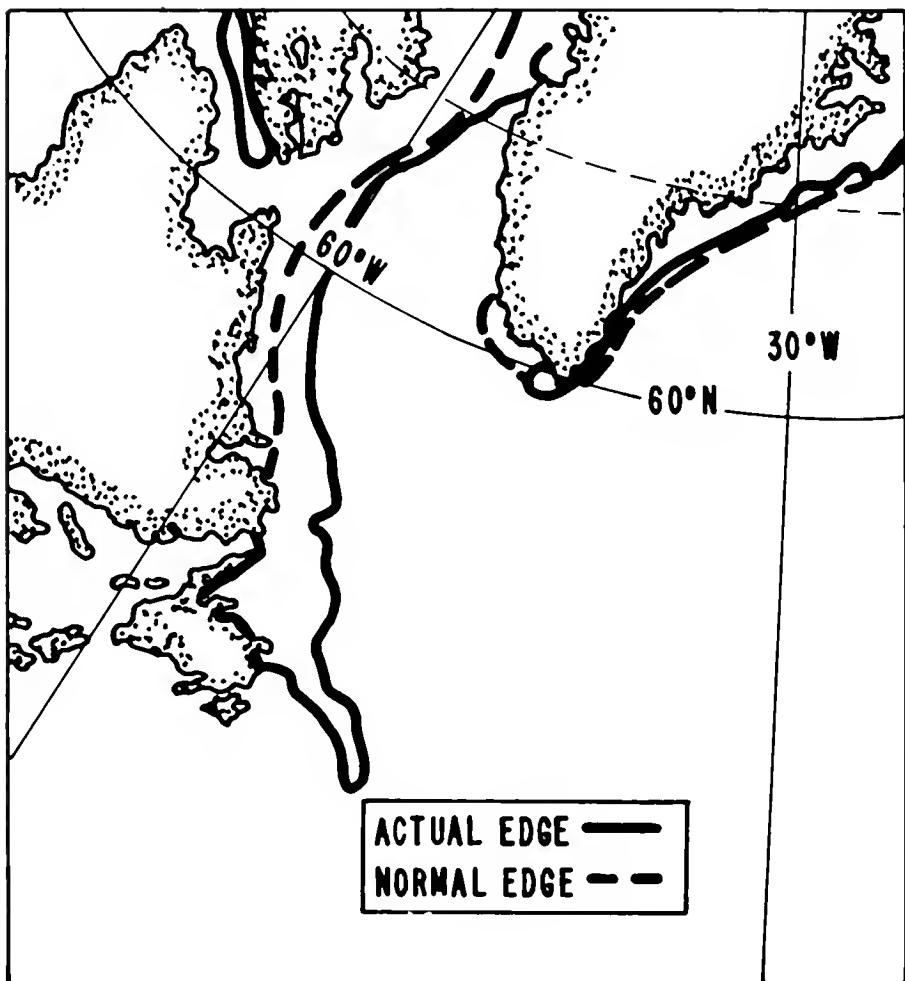

FIGURE 67. Normal sea ice edge compared with May 1972 sea ice edge
(after Sanderson, 1972 c).

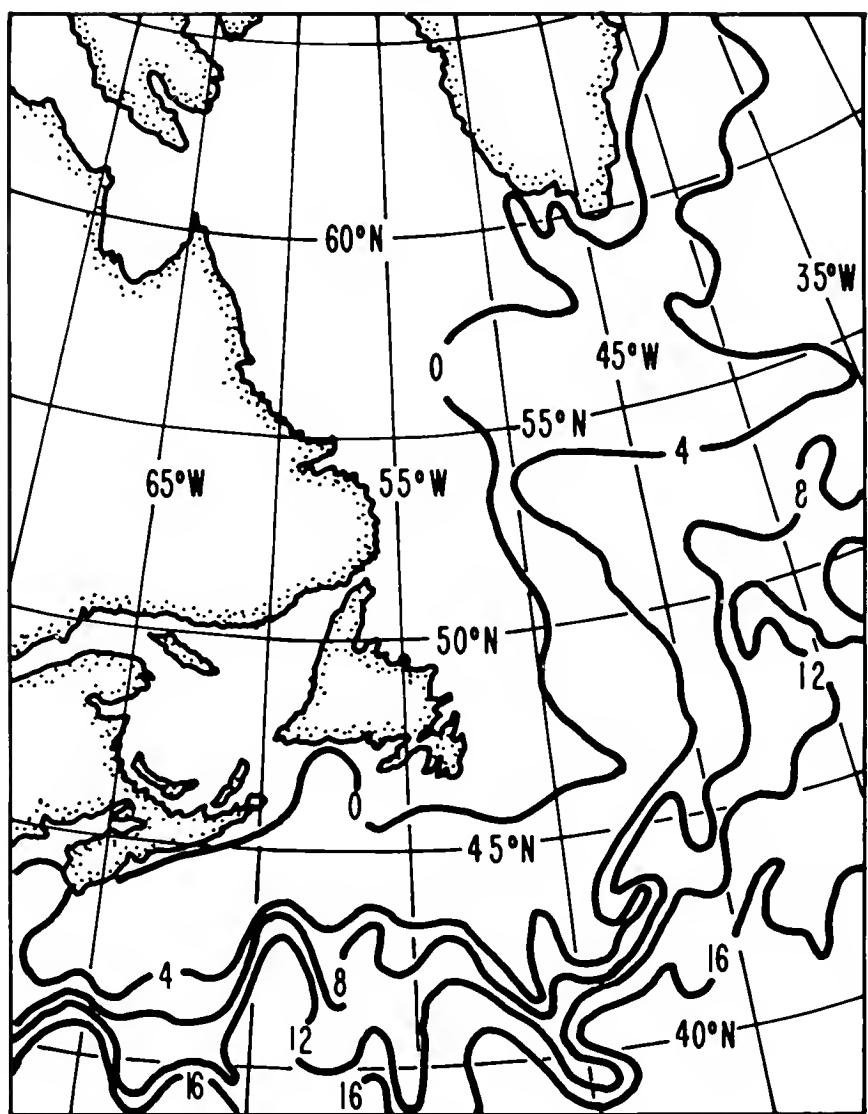

FIGURE 68. Mean sea surface temperatures ($^{\circ}\text{C}$) for March 1972
(after Royal Meteorological Office, 1972 a).

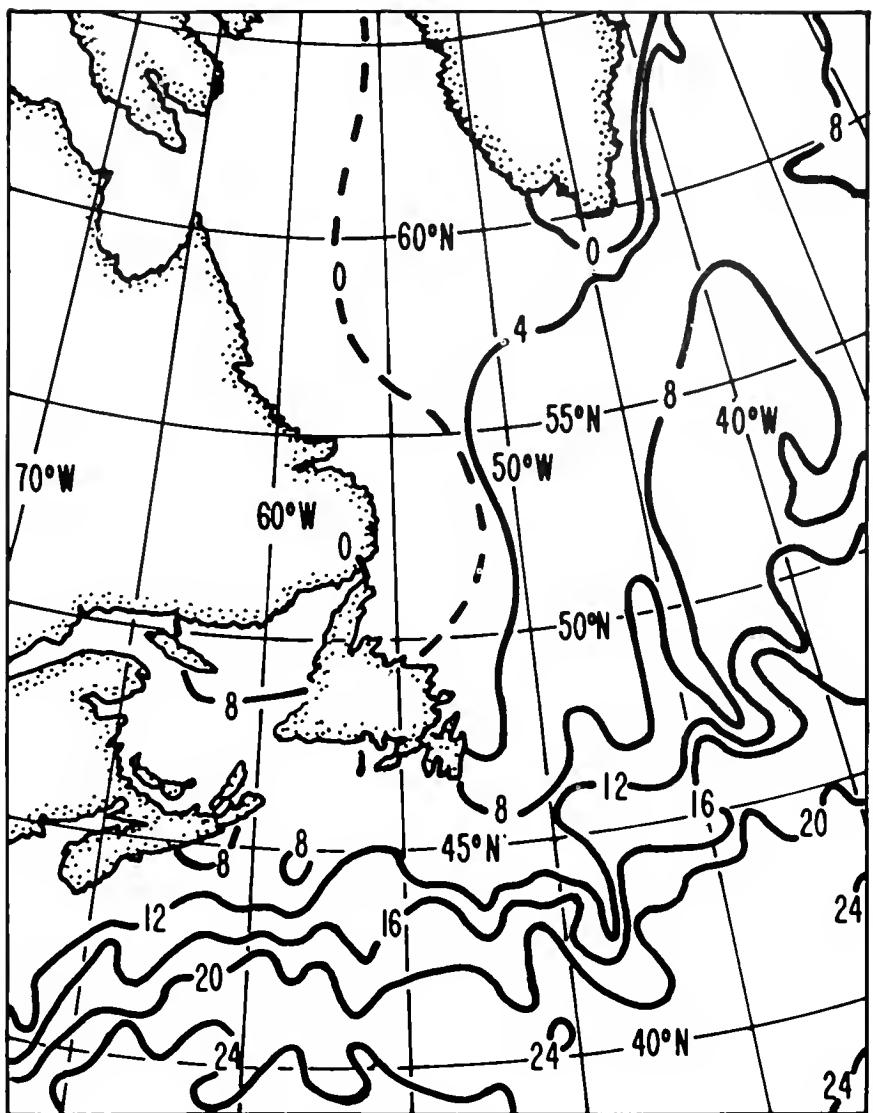

FIGURE 69. Mean sea surface temperature ($^{\circ}\text{C}$) for June 1972
(after Royal Meteorological Office, 1972 b).

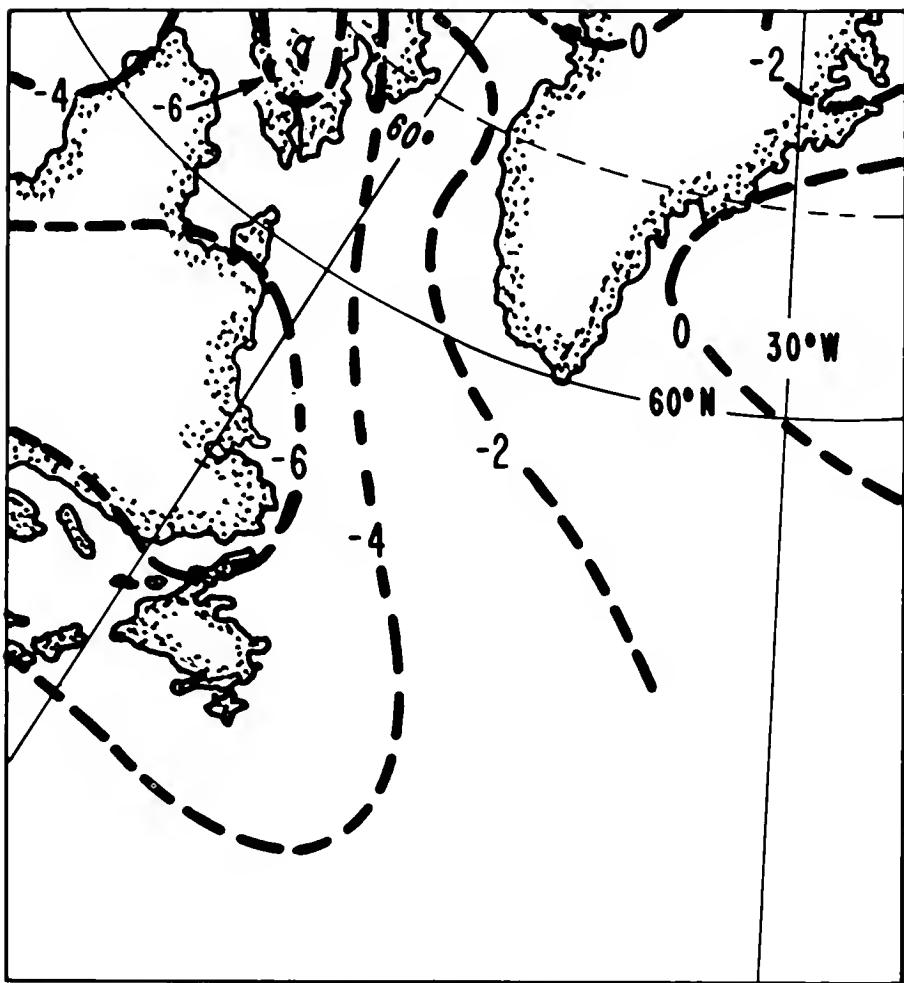

FIGURE 70. Air temperature anomaly for February 1972
(after Sanderson, 1972 B). Contour intervals 2°C .

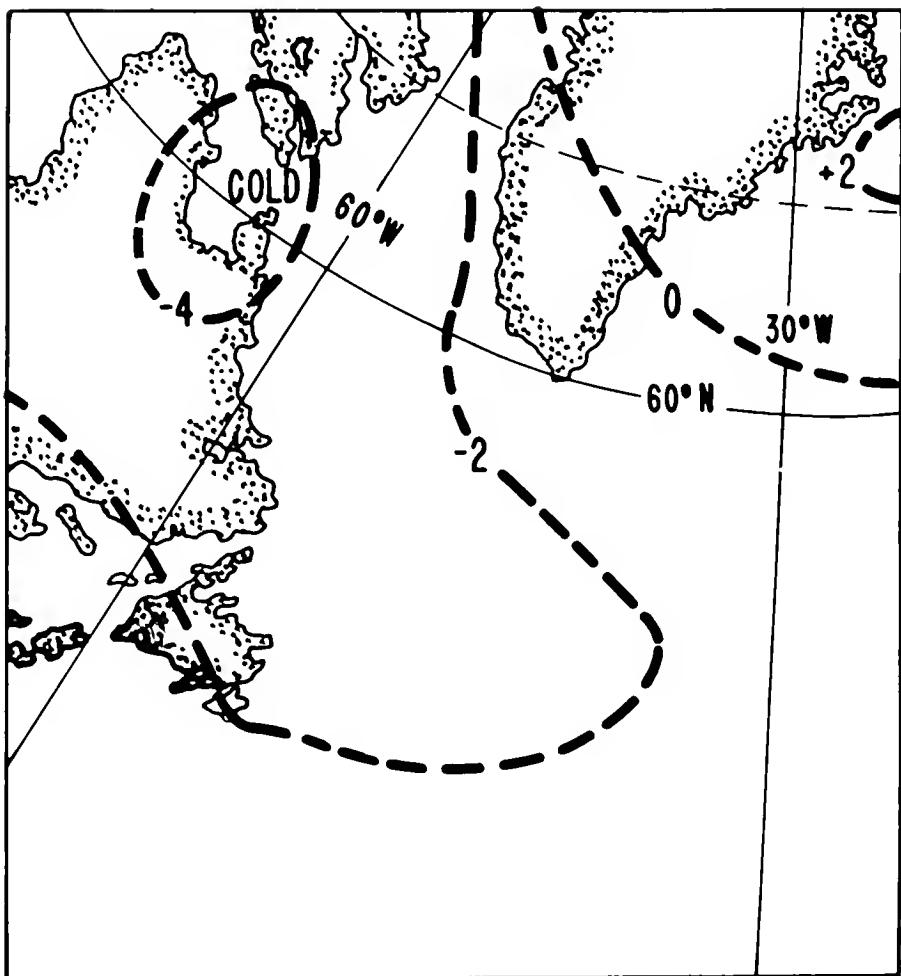

FIGURE 71. Air temperature anomaly for May 1972
(after Sanderson, 1972 e). Contour intervals 2 °C.

APPENDIX A

OCEANOGRAPHIC DATA

Cruises Listed

| Table | | Page |
|-------|-------------------------------------|------|
| I. | CGC SHERMAN November 1972 ----- | 80 |
| II. | CGC SPENCER September 1972 ----- | 85 |
| III. | CGC GALLATIN March 1971 ----- | 89 |
| IV. | CGC CAMPBELL July 1971 ----- | 95 |
| V. | CGC CHASE August 1971 ----- | 101 |
| VI. | CGC DALLAS November 1971 ----- | 107 |
| VII. | CGC SHERMAN March 1972 ----- | 114 |
| VIII. | CGC SHERMAN August 1972 ----- | 120 |
| IX. | CGC GALLATIN December 1972 ----- | 127 |
| X. | CGC HAMILTON September 1972 ----- | 132 |
| XI. | CGC DALLAS March 1971 ----- | 139 |
| XII. | CGC GALLATIN January 1972 ----- | 151 |
| XIII. | CGC EVERGREEN April-June 1972 ----- | 158 |

Codes Utilized

To facilitate use of the oceanographic station data listing, entry headings which are not self-explanatory are described below.

Latitude ----- Degrees and minutes of latitude.

Longitude ----- Degrees and minutes of longitude.

Depth to bottom ----- Uncorrected soundings in meters.

Wave observations:

| | |
|------|--|
| DIR. | Rounded to nearest multiple of 10 degrees. |
| HGT. | Increments of $\frac{1}{2}$ meter. Sum of 5 meters plus increments of $\frac{1}{2}$ meters if 50 is added to direction. |
| PER. | If numerals 2 through 9 are entered, period in seconds is either twice the numeric entry or 2X (numeric entry)+1. 0=20 or 21 sec. 1=over 21 seconds. X=calm or not determined. |
| SEA | Sea state according to WMO Code 3700. |

| Code | Height | Code | Height |
|------|-----------|------|--------|
| 0 | 0m | 5 | 2.5-4m |
| 1 | 0-0.1m | 6 | 4-6m |
| 2 | 0.1-0.5m | 7 | 6-9m |
| 3 | 0.5-1.25m | 8 | 9-14m |
| 4 | 1.25-2.5m | 9 | >14m |

Weather Code ----- Weather according to WMO Code 4501.

| <i>Code</i> | | <i>Code</i> | |
|-------------|-------------------------------|-------------|------------------------------|
| 0 | Clear | 5 | Drizzle |
| 1 | Partly cloudy | 6 | Rain |
| 2 | Cont. layers of clouds | 7 | Snow and rain and snow mixed |
| 3 | Blowing snow, sandstorm, etc. | 8 | Shower(s) |
| 4 | Fog, haze, dust | 9 | Thunder-storm(s) |

Cloud Code

Type ----- Cloud type according to WMO Code 0500.

| <i>Code</i> | <i>Type</i> | <i>Code</i> | <i>Type</i> |
|-------------|--------------|-------------|---------------|
| 0 | Cirrus | 5 | Nimbostratus |
| 1 | Cirrocumulus | 6 | Stratocumulus |
| 2 | Cirrostratus | 7 | Stratus |
| 3 | Altocumulus | 8 | Cumulus |
| 4 | Altostratus | 9 | Cumulonimbus |

X Clouds not visible due to darkness, fog, or other analogous phenomena

Amount ----- Cloud amount in eighths. Entry of the numeral 9 indicates cloud amount could not be estimated.

Wind

Dir. ----- Rounded to nearest multiple of 10 degrees.

Speed ----- Wind speed in knots.

Barometer ----- Barometric pressure given in tens, units, and tenths of millibars.

Vis. Code ----- Visibility according to WMO Code 4300.

| <i>Code</i> | <i>Visibility</i> | <i>Code</i> | <i>Visibility</i> |
|-------------|-------------------|-------------|-------------------|
| 0 | Less than 50m | 5 | 2–4km |
| 1 | 50–200m | 6 | 4–10km |
| 2 | 200–500m | 7 | 10–20km |
| 3 | 500–1000m | 8 | 20–50km |
| 4 | 1–2km | 9 | 50km or more |

Dyn. Ht. ----- Dynamic height in dynamic meters with respect to 1000 decibar reference surface.

Messenger time ----- Entered in hours and tenths of an hour. Indicates the starting time for lowering the STD sensor.

Depth ----- Depth to nearest meter.

Temp. ----- Temperature to hundredths of a degree Celsius.

Sal. ----- Salinity to hundredths of a part per thousand.

Sig-t ----- Sigma-t value.
